Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, PostgreSQL will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes or their planner statistics have been updated since the previous use of the prepared statement. Also, if the value of `search_path` changes from one use to the next, the statement will be re-parsed using the new `search_path`. (This latter behavior is new as of PostgreSQL 9.3.) These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the `search_path`, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the `pg_prepared_statements` system view.

## Examples

Create a prepared statement for an `INSERT` statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS
    INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then execute it:

```
PREPARE usrrptplan (int) AS
    SELECT * FROM users u, logs l WHERE u.usrid=$1 AND
    u.usrid=l.usrid
```

```
AND l.date = $2;  
EXECUTE usrrptplan(1, current_date);
```

In this example, the data type of the second parameter is not specified, so it is inferred from the context in which \$2 is used.

## Compatibility

The SQL standard includes a `PREPARE` statement, but it is only for use in embedded SQL. This version of the `PREPARE` statement also uses a somewhat different syntax.

---

# PREPARE TRANSACTION

PREPARE TRANSACTION — prepare the current transaction for two-phase commit

## Synopsis

```
PREPARE TRANSACTION transaction_id
```

## Description

PREPARE TRANSACTION prepares the current transaction for two-phase commit. After this command, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a very high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with COMMIT PREPARED or ROLLBACK PREPARED, respectively. Those commands can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, PREPARE TRANSACTION is not unlike a ROLLBACK command: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the PREPARE TRANSACTION command fails for any reason, it becomes a ROLLBACK: the current transaction is canceled.

## Parameters

*transaction\_id*

An arbitrary identifier that later identifies this transaction for COMMIT PREPARED or ROLLBACK PREPARED. The identifier must be written as a string literal, and must be less than 200 bytes long. It must not be the same as the identifier used for any currently prepared transaction.

## Notes

PREPARE TRANSACTION is not intended for use in applications or interactive sessions. Its purpose is to allow an external transaction manager to perform atomic global transactions across multiple databases or other transactional resources. Unless you're writing a transaction manager, you probably shouldn't be using PREPARE TRANSACTION.

This command must be used inside a transaction block. Use BEGIN to start one.

It is not currently allowed to PREPARE a transaction that has executed any operations involving temporary tables or the session's temporary namespace, created any cursors WITH HOLD, or executed LISTEN, UNLISTEN, or NOTIFY. Those features are too tightly tied to the current session to be useful in a transaction to be prepared.

If the transaction modified any run-time parameters with SET (without the LOCAL option), those effects persist after PREPARE TRANSACTION, and will not be affected by any later COMMIT PREPARED or ROLLBACK PREPARED. Thus, in this one respect PREPARE TRANSACTION acts more like COMMIT than ROLLBACK.

All currently available prepared transactions are listed in the pg\_prepared\_xacts system view.

### Caution

It is unwise to leave transactions in the prepared state for a long time. This will interfere with the ability of `VACUUM` to reclaim storage, and in extreme cases could cause the database to shut down to prevent transaction ID wraparound (see Section 24.1.5). Keep in mind also that the transaction continues to hold whatever locks it held. The intended usage of the feature is that a prepared transaction will normally be committed or rolled back as soon as an external transaction manager has verified that other databases are also prepared to commit.

If you have not set up an external transaction manager to track prepared transactions and ensure they get closed out promptly, it is best to keep the prepared-transaction feature disabled by setting `max_prepared_transactions` to zero. This will prevent accidental creation of prepared transactions that might then be forgotten and eventually cause problems.

## Examples

Prepare the current transaction for two-phase commit, using `foobar` as the transaction identifier:

```
PREPARE TRANSACTION 'foobar';
```

## Compatibility

`PREPARE TRANSACTION` is a PostgreSQL extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

`COMMIT PREPARED`, `ROLLBACK PREPARED`

---

# REASSIGN OWNED

REASSIGN OWNED — change the ownership of database objects owned by a database role

## Synopsis

```
REASSIGN OWNED BY { old_role | CURRENT_ROLE | CURRENT_USER |  
SESSION_USER } [, ...]  
                TO { new_role | CURRENT_ROLE | CURRENT_USER |  
SESSION_USER }
```

## Description

REASSIGN OWNED instructs the system to change the ownership of database objects owned by any of the *old\_roles* to *new\_role*.

## Parameters

*old\_role*

The name of a role. The ownership of all the objects within the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to *new\_role*.

*new\_role*

The name of the role that will be made the new owner of the affected objects.

## Notes

REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED does not affect objects within other databases, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

REASSIGN OWNED requires membership on both the source role(s) and the target role.

The DROP OWNED command is an alternative that simply drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect any privileges granted to the *old\_roles* on objects that are not owned by them. Likewise, it does not affect default privileges created with ALTER DEFAULT PRIVILEGES. Use DROP OWNED to revoke such privileges.

See Section 21.4 for more discussion.

## Compatibility

The REASSIGN OWNED command is a PostgreSQL extension.

## See Also

DROP OWNED, DROP ROLE, ALTER DATABASE

---

# REFRESH MATERIALIZED VIEW

REFRESH MATERIALIZED VIEW — replace the contents of a materialized view

## Synopsis

```
REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] name
[ WITH [ NO ] DATA ]
```

## Description

REFRESH MATERIALIZED VIEW completely replaces the contents of a materialized view. To execute this command you must have the **MAINTAIN** privilege on the materialized view. The old contents are discarded. If **WITH DATA** is specified (or defaults) the backing query is executed to provide the new data, and the materialized view is left in a scannable state. If **WITH NO DATA** is specified no new data is generated and the materialized view is left in an unscannable state.

**CONCURRENTLY** and **WITH NO DATA** may not be specified together.

## Parameters

**CONCURRENTLY**

Refresh the materialized view without locking out concurrent selects on the materialized view. Without this option a refresh which affects a lot of rows will tend to use fewer resources and complete more quickly, but could block other connections which are trying to read from the materialized view. This option may be faster in cases where a small number of rows are affected.

This option is only allowed if there is at least one **UNIQUE** index on the materialized view which uses only column names and includes all rows; that is, it must not be an expression index or include a **WHERE** clause.

This option can only be used when the materialized view is already populated.

Even with this option only one **REFRESH** at a time may run against any one materialized view.

*name*

The name (optionally schema-qualified) of the materialized view to refresh.

## Notes

If there is an **ORDER BY** clause in the materialized view's defining query, the original contents of the materialized view will be ordered that way; but **REFRESH MATERIALIZED VIEW** does not guarantee to preserve that ordering.

While **REFRESH MATERIALIZED VIEW** is running, the `search_path` is temporarily changed to `pg_catalog, pg_temp`.

## Examples

This command will replace the contents of the materialized view called `order_summary` using the query from the materialized view's definition, and leave it in a scannable state:

```
REFRESH MATERIALIZED VIEW order_summary;
```

This command will free storage associated with the materialized view `annual_statistics_basis` and leave it in an unscannable state:

```
REFRESH MATERIALIZED VIEW annual_statistics_basis WITH NO DATA;
```

## Compatibility

`REFRESH MATERIALIZED VIEW` is a PostgreSQL extension.

## See Also

`CREATE MATERIALIZED VIEW`, `ALTER MATERIALIZED VIEW`, `DROP MATERIALIZED VIEW`

---

# REINDEX

REINDEX — rebuild indexes

## Synopsis

```
REINDEX [ ( option [, ...] ) ] { INDEX | TABLE | SCHEMA }  
[ CONCURRENTLY ] name  
REINDEX [ ( option [, ...] ) ] { DATABASE | SYSTEM }  
[ CONCURRENTLY ] [ name ]
```

where *option* can be one of:

```
CONCURRENTLY [ boolean ]  
TABLESPACE new_tablespace  
VERBOSE [ boolean ]
```

## Description

REINDEX rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use REINDEX:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes can become corrupted due to software bugs or hardware failures. REINDEX provides a recovery method.
- An index has become “bloated”, that is it contains many empty or nearly-empty pages. This can occur with B-tree indexes in PostgreSQL under certain uncommon access patterns. REINDEX provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages. See Section 24.2 for more information.
- You have altered a storage parameter (such as fillfactor) for an index, and wish to ensure that the change has taken full effect.
- If an index build fails with the CONCURRENTLY option, this index is left as “invalid”. Such indexes are useless but it can be convenient to use REINDEX to rebuild them. Note that only REINDEX INDEX is able to perform a concurrent build on an invalid index.

## Parameters

### INDEX

Recreate the specified index. This form of REINDEX cannot be executed inside a transaction block when used with a partitioned index.

### TABLE

Recreate all indexes of the specified table. If the table has a secondary “TOAST” table, that is reindexed as well. This form of REINDEX cannot be executed inside a transaction block when used with a partitioned table.

### SCHEMA

Recreate all indexes of the specified schema. If a table of this schema has a secondary “TOAST” table, that is reindexed as well. Indexes on shared system catalogs are also processed. This form of REINDEX cannot be executed inside a transaction block.

**DATABASE**

Recreate all indexes within the current database, except system catalogs. Indexes on system catalogs are not processed. This form of **REINDEX** cannot be executed inside a transaction block.

**SYSTEM**

Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of **REINDEX** cannot be executed inside a transaction block.

*name*

The name of the specific index, table, or database to be reindexed. Index and table names can be schema-qualified. Presently, **REINDEX DATABASE** and **REINDEX SYSTEM** can only reindex the current database. Their parameter is optional, and it must match the current database's name.

**CONCURRENTLY**

When this option is used, PostgreSQL will rebuild the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index rebuild locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see *Rebuilding Indexes Concurrently* below.

For temporary tables, **REINDEX** is always non-concurrent, as no other session can access them, and non-concurrent reindex is cheaper.

**TABLESPACE**

Specifies that indexes will be rebuilt on a new tablespace.

**VERBOSE**

Prints a progress report as each index is reindexed at **INFO** level.

*boolean*

Specifies whether the selected option should be turned on or off. You can write **TRUE**, **ON**, or **1** to enable the option, and **FALSE**, **OFF**, or **0** to disable it. The *boolean* value can also be omitted, in which case **TRUE** is assumed.

*new\_tablespace*

The tablespace where indexes will be rebuilt.

## Notes

If you suspect corruption of an index on a user table, you can simply rebuild that index, or all indexes on the table, using **REINDEX INDEX** or **REINDEX TABLE**.

Things are more difficult if you need to recover from corruption of an index on a system table. In this case it's important for the system to not have used any of the suspect indexes itself. (Indeed, in this sort of scenario you might find that server processes are crashing immediately at start-up, due to reliance on the corrupted indexes.) To recover safely, the server must be started with the **-P** option, which prevents it from using indexes for system catalog lookups.

One way to do this is to shut down the server and start a single-user PostgreSQL server with the **-P** option included on its command line. Then, **REINDEX DATABASE**, **REINDEX SYSTEM**, **REINDEX TABLE**, or **REINDEX INDEX** can be issued, depending on how much you want to reconstruct. If in doubt, use **REINDEX SYSTEM** to select reconstruction of all system indexes in the database. Then

quit the single-user server session and restart the regular server. See the postgres reference page for more information about how to interact with the single-user server interface.

Alternatively, a regular server session can be started with `-P` included in its command line options. The method for doing this varies across clients, but in all libpq-based clients, it is possible to set the `PGOPTIONS` environment variable to `-P` before starting the client. Note that while this method does not require locking out other clients, it might still be wise to prevent other users from connecting to the damaged database until repairs have been completed.

`REINDEX` is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. `REINDEX` locks out writes but not reads of the index's parent table. It also takes an `ACCESS EXCLUSIVE` lock on the specific index being processed, which will block reads that attempt to use that index. In particular, the query planner tries to take an `ACCESS SHARE` lock on every index of the table, regardless of the query, and so `REINDEX` blocks virtually any queries except for some prepared queries whose plan has been cached and which don't use this very index. In contrast, `DROP INDEX` momentarily takes an `ACCESS EXCLUSIVE` lock on the parent table, blocking both writes and reads. The subsequent `CREATE INDEX` locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads might be forced into expensive sequential scans.

While `REINDEX` is running, the `search_path` is temporarily changed to `pg_catalog, pg_temp`.

Reindexing a single index or table requires having the `MAINTAIN` privilege on the table. Note that while `REINDEX` on a partitioned index or table requires having the `MAINTAIN` privilege on the partitioned table, such commands skip the privilege checks when processing the individual partitions. Reindexing a schema or database requires being the owner of that schema or database or having privileges of the `pg_maintain` role. Note specifically that it's thus possible for non-superusers to rebuild indexes of tables owned by other users. However, as a special exception, `REINDEX DATABASE`, `REINDEX SCHEMA`, and `REINDEX SYSTEM` will skip indexes on shared catalogs unless the user has the `MAINTAIN` privilege on the catalog.

Reindexing partitioned indexes or partitioned tables is supported with `REINDEX INDEX` or `REINDEX TABLE`, respectively. Each partition of the specified partitioned relation is reindexed in a separate transaction. Those commands cannot be used inside a transaction block when working on a partitioned table or index.

When using the `TABLESPACE` clause with `REINDEX` on a partitioned index or table, only the tablespace references of the leaf partitions are updated. As partitioned indexes are not updated, it is recommended to separately use `ALTER TABLE ONLY` on them so as any new partitions attached inherit the new tablespace. On failure, it may not have moved all the indexes to the new tablespace. Re-running the command will rebuild all the leaf partitions and move previously-unprocessed indexes to the new tablespace.

If `SCHEMA`, `DATABASE` or `SYSTEM` is used with `TABLESPACE`, system relations are skipped and a single `WARNING` will be generated. Indexes on `TOAST` tables are rebuilt, but not moved to the new tablespace.

## Rebuilding Indexes Concurrently

Rebuilding an index can interfere with regular operation of a database. Normally PostgreSQL locks the table whose index is rebuilt against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index rebuild is finished. This could have a severe effect if the system is a live production database. Very large tables can take many hours to be indexed, and even for smaller tables, an index rebuild can lock out writers for periods that are unacceptably long for a production system.

PostgreSQL supports rebuilding indexes with minimum locking of writes. This method is invoked by specifying the `CONCURRENTLY` option of `REINDEX`. When this option is used, PostgreSQL must perform two scans of the table for each index that needs to be rebuilt and wait for termination of all

existing transactions that could potentially use the index. This method requires more total work than a standard index rebuild and takes significantly longer to complete as it needs to wait for unfinished transactions that might modify the index. However, since it allows normal operations to continue while the index is being rebuilt, this method is useful for rebuilding indexes in a production environment. Of course, the extra CPU, memory and I/O load imposed by the index rebuild may slow down other operations.

The following steps occur in a concurrent reindex. Each step is run in a separate transaction. If there are multiple indexes to be rebuilt, then each step loops through all the indexes before moving to the next step.

1. A new transient index definition is added to the catalog `pg_index`. This definition will be used to replace the old index. A `SHARE UPDATE EXCLUSIVE` lock at session level is taken on the indexes being reindexed as well as their associated tables to prevent any schema modification while processing.
2. A first pass to build the index is done for each new index. Once the index is built, its flag `pg_index.indisready` is switched to “true” to make it ready for inserts, making it visible to other sessions once the transaction that performed the build is finished. This step is done in a separate transaction for each index.
3. Then a second pass is performed to add tuples that were added while the first pass was running. This step is also done in a separate transaction for each index.
4. All the constraints that refer to the index are changed to refer to the new index definition, and the names of the indexes are changed. At this point, `pg_index.invalid` is switched to “true” for the new index and to “false” for the old, and a cache invalidation is done causing all sessions that referenced the old index to be invalidated.
5. The old indexes have `pg_index.indisready` switched to “false” to prevent any new tuple insertions, after waiting for running queries that might reference the old index to complete.
6. The old indexes are dropped. The `SHARE UPDATE EXCLUSIVE` session locks for the indexes and the table are released.

If a problem arises while rebuilding the indexes, such as a uniqueness violation in a unique index, the `REINDEX` command will fail but leave behind an “invalid” new index in addition to the pre-existing one. This index will be ignored for querying purposes because it might be incomplete; however it will still consume update overhead. The `psql \d` command will report such an index as `INVALID`:

```
postgres=# \d tab
          Table "public.tab"
  Column | Type   | Modifiers
-----+-----+-----
   col   | integer |
Indexes:
    "idx" btree (col)
    "idx_ccnew" btree (col) INVALID
```

If the index marked `INVALID` is suffixed `_ccnew`, then it corresponds to the transient index created during the concurrent operation, and the recommended recovery method is to drop it using `DROP INDEX`, then attempt `REINDEX CONCURRENTLY` again. If the invalid index is instead suffixed `_ccold`, it corresponds to the original index which could not be dropped; the recommended recovery method is to just drop said index, since the rebuild proper has been successful. A nonzero number may be appended to the suffix of the invalid index names to keep them unique, like `_ccnew1`, `_ccold2`, etc.

Regular index builds permit other regular index builds on the same table to occur simultaneously, but only one concurrent index build can occur on a table at a time. In both cases, no other types of schema

modification on the table are allowed meanwhile. Another difference is that a regular **REINDEX TABLE** or **REINDEX INDEX** command can be performed within a transaction block, but **REINDEX CONCURRENTLY** cannot.

Like any long-running transaction, **REINDEX** on a table can affect which tuples can be removed by concurrent **VACUUM** on any other table.

**REINDEX SYSTEM** does not support **CONCURRENTLY** since system catalogs cannot be reindexed concurrently.

Furthermore, indexes for exclusion constraints cannot be reindexed concurrently. If such an index is named directly in this command, an error is raised. If a table or database with exclusion constraint indexes is reindexed concurrently, those indexes will be skipped. (It is possible to reindex such indexes without the **CONCURRENTLY** option.)

Each backend running **REINDEX** will report its progress in the `pg_stat_progress_create_index` view. See Section 27.4.4 for details.

## Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table `my_table`:

```
REINDEX TABLE my_table;
```

Rebuild all indexes in a particular database, without trusting the system indexes to be valid already:

```
$ export PGOPTIONS="-P"
$ psql broken_db
...
broken_db=> REINDEX DATABASE broken_db;
broken_db=> \q
```

Rebuild indexes for a table, without blocking read and write operations on involved relations while reindexing is in progress:

```
REINDEX TABLE CONCURRENTLY my_broken_table;
```

## Compatibility

There is no **REINDEX** command in the SQL standard.

## See Also

**CREATE INDEX**, **DROP INDEX**, `reindexdb`, Section 27.4.4

---

# RELEASE SAVEPOINT

RELEASE SAVEPOINT — release a previously defined savepoint

## Synopsis

```
RELEASE [ SAVEPOINT ] savepoint_name
```

## Description

RELEASE SAVEPOINT releases the named savepoint and all active savepoints that were created after the named savepoint, and frees their resources. All changes made since the creation of the savepoint that didn't already get rolled back are merged into the transaction or savepoint that was active when the named savepoint was created. Changes made after RELEASE SAVEPOINT will also be part of this active transaction or savepoint.

## Parameters

*savepoint\_name*

The name of the savepoint to release.

## Notes

Specifying a savepoint name that was not previously defined is an error.

It is not possible to release a savepoint when the transaction is in an aborted state; to do that, use ROLLBACK TO SAVEPOINT.

If multiple savepoints have the same name, only the most recently defined unreleased one is released. Repeated commands will release progressively older savepoints.

## Examples

To establish and later release a savepoint:

```
BEGIN;  
  INSERT INTO table1 VALUES (3);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (4);  
  RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

A more complex example with multiple nested subtransactions:

```
BEGIN;  
  INSERT INTO table1 VALUES (1);  
  SAVEPOINT sp1;  
  INSERT INTO table1 VALUES (2);  
  SAVEPOINT sp2;
```

```
INSERT INTO table1 VALUES (3);  
RELEASE SAVEPOINT sp2;  
INSERT INTO table1 VALUES (4)); -- generates an error
```

In this example, the application requests the release of the savepoint `sp2`, which inserted 3. This changes the insert's transaction context to `sp1`. When the statement attempting to insert value 4 generates an error, the insertion of 2 and 4 are lost because they are in the same, now-rolled back savepoint, and value 3 is in the same transaction context. The application can now only choose one of these two commands, since all other commands will be ignored:

```
ROLLBACK;  
ROLLBACK TO SAVEPOINT sp1;
```

Choosing `ROLLBACK` will abort everything, including value 1, whereas `ROLLBACK TO SAVEPOINT sp1` will retain value 1 and allow the transaction to continue.

## Compatibility

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but PostgreSQL allows it to be omitted.

## See Also

`BEGIN`, `COMMIT`, `ROLLBACK`, `ROLLBACK TO SAVEPOINT`, `SAVEPOINT`

---

# RESET

RESET — restore the value of a run-time parameter to the default value

## Synopsis

```
RESET configuration_parameter
RESET ALL
```

## Description

RESET restores run-time parameters to their default values. RESET is an alternative spelling for

```
SET configuration_parameter TO DEFAULT
```

Refer to SET for details.

The default value is defined as the value that the parameter would have had, if no SET had ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the configuration file, command-line options, or per-database or per-user default settings. This is subtly different from defining it as “the value that the parameter had at session start”, because if the value came from the configuration file, it will be reset to whatever is specified by the configuration file now. See Chapter 19 for details.

The transactional behavior of RESET is the same as SET: its effects will be undone by transaction rollback.

## Parameters

*configuration\_parameter*

Name of a settable run-time parameter. Available parameters are documented in Chapter 19 and on the SET reference page.

ALL

Resets all settable run-time parameters to default values.

## Examples

Set the `timezone` configuration variable to its default value:

```
RESET timezone;
```

## Compatibility

RESET is a PostgreSQL extension.

## See Also

SET, SHOW

    ON TYPE type_name [, ...]
    FROM role_specification [, ...]
    [ GRANTED BY role_specification ]

```

```
[ CASCADE | RESTRICT ]
```

```
REVOKE [ { ADMIN | INHERIT | SET } OPTION FOR ]  
      role_name [, ...] FROM role_specification [, ...]  
      [ GRANTED BY role_specification ]  
      [ CASCADE | RESTRICT ]
```

where *role\_specification* can be:

```
[ GROUP ] role_name  
| PUBLIC  
| CURRENT_ROLE  
| CURRENT_USER  
| SESSION_USER
```

## Description

The REVOKE command revokes previously granted privileges from one or more roles. The key word PUBLIC refers to the implicitly defined group of all roles.

See the description of the GRANT command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC. Thus, for example, revoking SELECT privilege from PUBLIC does not necessarily mean that all roles have lost SELECT privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking SELECT from a user might not prevent that user from using SELECT if PUBLIC or another membership role still has SELECT rights.

If GRANT OPTION FOR is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a user holds a privilege with grant option and has granted it to other users then the privileges held by those other users are called dependent privileges. If the privilege or the grant option held by the first user is being revoked and dependent privileges exist, those dependent privileges are also revoked if CASCADE is specified; if it is not, the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of users that is traceable to the user that is the subject of this REVOKE command. Thus, the affected users might effectively keep the privilege if it was also granted through other users.

When revoking privileges on a table, the corresponding column privileges (if any) are automatically revoked on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

When revoking membership in a role, GRANT OPTION is instead called ADMIN OPTION, but the behavior is similar. Note that, in releases prior to PostgreSQL 16, dependent privileges were not tracked for grants of role membership, and thus CASCADE had no effect for role membership. This is no longer the case. Note also that this form of the command does not allow the noise word GROUP in *role\_specification*.

Just as ADMIN OPTION can be removed from an existing role grant, it is also possible to revoke INHERIT OPTION or SET OPTION. This is equivalent to setting the value of the corresponding option to FALSE.

## Notes

A user can only revoke privileges that were granted directly by that user. If, for example, user A has granted a privilege with grant option to user B, and user B has in turn granted it to user C, then user

A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the **CASCADE** option so that the privilege is in turn revoked from user C. For another example, if both A and B have granted the same privilege to C, A can revoke their own grant but not B's grant, so C will still effectively have the privilege.

When a non-owner of an object attempts to **REVOKE** privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will revoke only those privileges for which the user has grant options. The **REVOKE ALL PRIVILEGES** forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a **GRANT** or **REVOKE** command, the command is performed as though it were issued by the owner of the affected object. (Since roles do not have owners, in the case of a **GRANT** of role membership, the command is performed as though it were issued by the bootstrap superuser.) Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of **CASCADE** as stated above.

**REVOKE** can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges **WITH GRANT OPTION** on the object. In this case the command is performed as though it were issued by the containing role that actually owns the object or holds the privileges **WITH GRANT OPTION**. For example, if table **t1** is owned by role **g1**, of which role **u1** is a member, then **u1** can revoke privileges on **t1** that are recorded as being granted by **g1**. This would include grants made by **u1** as well as by other members of role **g1**.

If the role executing **REVOKE** holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use **SET ROLE** to become the specific role you want to do the **REVOKE** as. Failure to do so might lead to revoking privileges other than the ones you intended, or not revoking anything at all.

See Section 5.8 for more information about specific privilege types, as well as how to inspect objects' privileges.

## Examples

Revoke insert privilege for the public on table **films**:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from user **manuel** on view **kinds**:

```
REVOKE ALL PRIVILEGES ON kinds FROM manuel;
```

Note that this actually means “revoke all privileges that I granted”.

Revoke membership in role **admins** from user **joe**:

```
REVOKE admins FROM joe;
```

## Compatibility

The compatibility notes of the **GRANT** command apply analogously to **REVOKE**. The keyword **RESTRICT** or **CASCADE** is required according to the standard, but PostgreSQL assumes **RESTRICT** by default.

---

# ROLLBACK

ROLLBACK — abort the current transaction

## Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

## Description

ROLLBACK rolls back the current transaction and causes all the updates made by the transaction to be discarded.

## Parameters

WORK  
TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new (not aborted) transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

## Notes

Use COMMIT to successfully terminate a transaction.

Issuing ROLLBACK outside of a transaction block emits a warning and otherwise has no effect. ROLLBACK AND CHAIN outside of a transaction block is an error.

## Examples

To abort all changes:

```
ROLLBACK;
```

## Compatibility

The command ROLLBACK conforms to the SQL standard. The form ROLLBACK TRANSACTION is a PostgreSQL extension.

## See Also

BEGIN, COMMIT, ROLLBACK TO SAVEPOINT

---

# ROLLBACK PREPARED

ROLLBACK PREPARED — cancel a transaction that was earlier prepared for two-phase commit

## Synopsis

```
ROLLBACK PREPARED transaction_id
```

## Description

ROLLBACK PREPARED rolls back a transaction that is in prepared state.

## Parameters

*transaction\_id*

The transaction identifier of the transaction that is to be rolled back.

## Notes

To roll back a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is rolled back immediately.

All currently available prepared transactions are listed in the `pg_prepared_xacts` system view.

## Examples

Roll back the transaction identified by the transaction identifier `foobar`:

```
ROLLBACK PREPARED 'foobar';
```

## Compatibility

ROLLBACK PREPARED is a PostgreSQL extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

PREPARE TRANSACTION, COMMIT PREPARED

---

# ROLLBACK TO SAVEPOINT

ROLLBACK TO SAVEPOINT — roll back to a savepoint

## Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] savepoint_name
```

## Description

Roll back all commands that were executed after the savepoint was established and then start a new subtransaction at the same transaction level. The savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

## Parameters

*savepoint\_name*

The savepoint to roll back to.

## Notes

Use `RELEASE SAVEPOINT` to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a `FETCH` or `MOVE` command inside a savepoint that is later rolled back, the cursor remains at the position that `FETCH` left it pointing to (that is, the cursor motion caused by `FETCH` is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) *are* rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

## Examples

To undo the effects of the commands executed after `my_savepoint` was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by savepoint rollback:

```
BEGIN;
```

```
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
```

```
SAVEPOINT foo;

FETCH 1 FROM foo;
?column?
-----
      1

ROLLBACK TO SAVEPOINT foo;

FETCH 1 FROM foo;
?column?
-----
      2

COMMIT;
```

## Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but PostgreSQL and Oracle allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [ NO ] CHAIN` which is not currently supported by PostgreSQL. Otherwise, this command conforms to the SQL standard.

## See Also

`BEGIN`, `COMMIT`, `RELEASE SAVEPOINT`, `ROLLBACK`, `SAVEPOINT`

---

# SAVEPOINT

SAVEPOINT — define a new savepoint within the current transaction

## Synopsis

```
SAVEPOINT savepoint_name
```

## Description

SAVEPOINT establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

## Parameters

*savepoint\_name*

The name to give to the new savepoint. If savepoints with the same name already exist, they will be inaccessible until newer identically-named savepoints are released.

## Notes

Use ROLLBACK TO to rollback to a savepoint. Use RELEASE SAVEPOINT to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

## Examples

To establish a savepoint and later undo the effects of all commands executed after it was established:

```
BEGIN;  
  INSERT INTO table1 VALUES (1);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (2);  
  ROLLBACK TO SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (3);  
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;  
  INSERT INTO table1 VALUES (3);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (4);  
  RELEASE SAVEPOINT my_savepoint;
```

```
COMMIT;
```

The above transaction will insert both 3 and 4.

To use a single savepoint name:

```
BEGIN;
  INSERT INTO table1 VALUES (1);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (2);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (3);

  -- rollback to the second savepoint
  ROLLBACK TO SAVEPOINT my_savepoint;
  SELECT * FROM table1;                -- shows rows 1 and 2

  -- release the second savepoint
  RELEASE SAVEPOINT my_savepoint;

  -- rollback to the first savepoint
  ROLLBACK TO SAVEPOINT my_savepoint;
  SELECT * FROM table1;                -- shows only row 1
COMMIT;
```

The above transaction shows row 3 being rolled back first, then row 2.

## Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In PostgreSQL, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint with `RELEASE SAVEPOINT` will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

    VIEW object_name
} IS { string_literal | NULL }

where aggregate_signature is:

* |
[ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ]
[ argname ] argtype [ , ... ]
```

## Description

SECURITY LABEL applies a security label to a database object. An arbitrary number of security labels, one per label provider, can be associated with a given database object. Label providers are loadable modules which register themselves by using the function `register_label_provider`.

### Note

`register_label_provider` is not an SQL function; it can only be called from C code loaded into the backend.

The label provider determines whether a given label is valid and whether it is permissible to assign that label to a given object. The meaning of a given label is likewise at the discretion of the label provider. PostgreSQL places no restrictions on whether or how a label provider must interpret security labels; it merely provides a mechanism for storing them. In practice, this facility is intended to allow integration with label-based mandatory access control (MAC) systems such as SELinux. Such systems make all access control decisions based on object labels, rather than traditional discretionary access control (DAC) concepts such as users and groups.

You must own the database object to use `SECURITY LABEL`.

## Parameters

*object\_name*  
*table\_name.column\_name*  
*aggregate\_name*  
*function\_name*  
*procedure\_name*  
*routine\_name*

The name of the object to be labeled. Names of objects that reside in schemas (tables, functions, etc.) can be schema-qualified.

*provider*

The name of the provider with which this label is to be associated. The named provider must be loaded and must consent to the proposed labeling operation. If exactly one provider is loaded, the provider name may be omitted for brevity.

*argmode*

The mode of a function, procedure, or aggregate argument: `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `SECURITY LABEL` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

*argname*

The name of a function, procedure, or aggregate argument. Note that `SECURITY LABEL` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type of a function, procedure, or aggregate argument.

*large\_object\_oid*

The OID of the large object.

`PROCEDURAL`

This is a noise word.

*string\_literal*

The new setting of the security label, written as a string literal.

`NULL`

Write `NULL` to drop the security label.

## Examples

The following example shows how the security label of a table could be set or changed:

```
SECURITY LABEL FOR selinux ON TABLE mytable IS  
'system_u:object_r:sepgsql_table_t:s0';
```

To remove the label:

```
SECURITY LABEL FOR selinux ON TABLE mytable IS NULL;
```

## Compatibility

There is no SECURITY LABEL command in the SQL standard.

      from_item join_type from_item { ON join_condition | USING
( join_column [, ...] ) [ AS join_using_alias ] }
      from_item NATURAL join_type from_item
      from_item CROSS JOIN from_item
```

and *grouping\_element* can be one of:

```
( )
expression
( expression [, ...] )
```

```
ROLLUP ( { expression | ( expression [, ...] ) } [, ...] )  
CUBE ( { expression | ( expression [, ...] ) } [, ...] )  
GROUPING SETS ( grouping_element [, ...] )
```

and *with\_query* is:

```
with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ]  
MATERIALIZED ] ( select | values | insert | update | delete  
| merge )  
[ SEARCH { BREADTH | DEPTH } FIRST BY column_name [, ...]  
SET search_seq_col_name ]  
[ CYCLE column_name [, ...] SET cycle_mark_col_name  
[ TO cycle_mark_value DEFAULT cycle_mark_default ]  
USING cycle_path_col_name ]
```

```
TABLE [ ONLY ] table_name [ * ]
```

## Description

SELECT retrieves rows from zero or more tables. The general processing of SELECT is as follows:

1. All queries in the WITH list are computed. These effectively serve as temporary tables that can be referenced in the FROM list. A WITH query that is referenced more than once in FROM is computed only once, unless specified otherwise with NOT MATERIALIZED. (See WITH Clause below.)
2. All elements in the FROM list are computed. (Each element in the FROM list is a real or virtual table.) If more than one element is specified in the FROM list, they are cross-joined together. (See FROM Clause below.)
3. If the WHERE clause is specified, all rows that do not satisfy the condition are eliminated from the output. (See WHERE Clause below.)
4. If the GROUP BY clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the HAVING clause is present, it eliminates groups that do not satisfy the given condition. (See GROUP BY Clause and HAVING Clause below.) Although query output columns are nominally computed in the next step, they can also be referenced (by name or ordinal number) in the GROUP BY clause.
5. The actual output rows are computed using the SELECT output expressions for each selected row or row group. (See SELECT List below.)
6. SELECT DISTINCT eliminates duplicate rows from the result. SELECT DISTINCT ON eliminates rows that match on all the specified expressions. SELECT ALL (the default) will return all candidate rows, including duplicates. (See DISTINCT Clause below.)
7. Using the operators UNION, INTERSECT, and EXCEPT, the output of more than one SELECT statement can be combined to form a single result set. The UNION operator returns all rows that are in one or both of the result sets. The INTERSECT operator returns all rows that are strictly in both result sets. The EXCEPT operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless ALL is specified. The noise word DISTINCT can be added to explicitly specify eliminating duplicate rows. Notice that DISTINCT is the default behavior here, even though ALL is the default for SELECT itself. (See UNION Clause, INTERSECT Clause, and EXCEPT Clause below.)
8. If the ORDER BY clause is specified, the returned rows are sorted in the specified order. If ORDER BY is not given, the rows are returned in whatever order the system finds fastest to produce. (See ORDER BY Clause below.)

9. If the `LIMIT` (or `FETCH FIRST`) or `OFFSET` clause is specified, the `SELECT` statement only returns a subset of the result rows. (See `LIMIT` Clause below.)
10. If `FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE` or `FOR KEY SHARE` is specified, the `SELECT` statement locks the selected rows against concurrent updates. (See `The Locking Clause` below.)

You must have `SELECT` privilege on each column used in a `SELECT` command. The use of `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` or `FOR KEY SHARE` requires `UPDATE` privilege as well (for at least one column of each table so selected).

## Parameters

### WITH Clause

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a `SELECT`, `TABLE`, `VALUES`, `INSERT`, `UPDATE`, `DELETE`, or `MERGE` statement. When writing a data-modifying statement (`INSERT`, `UPDATE`, `DELETE`, or `MERGE`) in `WITH`, it is usual to include a `RETURNING` clause. It is the output of `RETURNING`, *not* the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If `RETURNING` is omitted, the statement is still executed, but it produces no output so it cannot be referenced as a table by the primary query.

A name (without schema qualification) must be specified for each `WITH` query. Optionally, a list of column names can be specified; if this is omitted, the column names are inferred from the subquery.

If `RECURSIVE` is specified, it allows a `SELECT` subquery to reference itself by name. Such a subquery must have the form

```
non_recursive_term UNION [ ALL | DISTINCT ] recursive_term
```

where the recursive self-reference must appear on the right-hand side of the `UNION`. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive `SELECT` query in a data-modifying statement. See Section 7.8 for an example.

Another effect of `RECURSIVE` is that `WITH` queries need not be ordered: a query can reference another one that is later in the list. (However, circular references, or mutual recursion, are not implemented.) Without `RECURSIVE`, `WITH` queries can only reference sibling `WITH` queries that are earlier in the `WITH` list.

When there are multiple queries in the `WITH` clause, `RECURSIVE` should be written only once, immediately after `WITH`. It applies to all queries in the `WITH` clause, though it has no effect on queries that do not use recursion or forward references.

The optional `SEARCH` clause computes a *search sequence column* that can be used for ordering the results of a recursive query in either breadth-first or depth-first order. The supplied column name list specifies the row key that is to be used for keeping track of visited rows. A column named *search\_seq\_col\_name* will be added to the result column list of the `WITH` query. This column can be ordered by in the outer query to achieve the respective ordering. See Section 7.8.2.1 for examples.

The optional `CYCLE` clause is used to detect cycles in recursive queries. The supplied column name list specifies the row key that is to be used for keeping track of visited rows. A column named *cycle\_mark\_col\_name* will be added to the result column list of the `WITH` query. This column will be set to *cycle\_mark\_value* when a cycle has been detected, else to *cycle\_mark\_default*. Furthermore, processing of the recursive union will stop when a cycle has been detected. *cycle\_mark\_value* and *cycle\_mark\_default* must be constants and they must be coercible

to a common data type, and the data type must have an inequality operator. (The SQL standard requires that they be Boolean constants or character strings, but PostgreSQL does not require that.) By default, `TRUE` and `FALSE` (of type `boolean`) are used. Furthermore, a column named *cycle\_path\_col\_name* will be added to the result column list of the `WITH` query. This column is used internally for tracking visited rows. See Section 7.8.2.2 for examples.

Both the `SEARCH` and the `CYCLE` clause are only valid for recursive `WITH` queries. The *with\_query* must be a `UNION` (or `UNION ALL`) of two `SELECT` (or equivalent) commands (no nested `UNIONS`). If both clauses are used, the column added by the `SEARCH` clause appears before the columns added by the `CYCLE` clause.

The primary query and the `WITH` queries are all (notionally) executed at the same time. This implies that the effects of a data-modifying statement in `WITH` cannot be seen from other parts of the query, other than by reading its `RETURNING` output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

A key property of `WITH` queries is that they are normally evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be executed once and only once, regardless of whether the primary query reads all or any of their output.

However, a `WITH` query can be marked `NOT MATERIALIZED` to remove this guarantee. In that case, the `WITH` query can be folded into the primary query much as though it were a simple sub-`SELECT` in the primary query's `FROM` clause. This results in duplicate computations if the primary query refers to that `WITH` query more than once; but if each such use requires only a few rows of the `WITH` query's total output, `NOT MATERIALIZED` can provide a net savings by allowing the queries to be optimized jointly. `NOT MATERIALIZED` is ignored if it is attached to a `WITH` query that is recursive or is not side-effect-free (i.e., is not a plain `SELECT` containing no volatile functions).

By default, a side-effect-free `WITH` query is folded into the primary query if it is used exactly once in the primary query's `FROM` clause. This allows joint optimization of the two query levels in situations where that should be semantically invisible. However, such folding can be prevented by marking the `WITH` query as `MATERIALIZED`. That might be useful, for example, if the `WITH` query is being used as an optimization fence to prevent the planner from choosing a bad plan. PostgreSQL versions before v12 never did such folding, so queries written for older versions might rely on `WITH` to act as an optimization fence.

See Section 7.8 for additional information.

## FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via `WHERE`) to restrict the returned rows to a small subset of the Cartesian product.

The `FROM` clause can contain the following elements:

### *table\_name*

The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified before the table name, only that table is scanned. If `ONLY` is not specified, the table and all its descendant tables (if any) are scanned. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

### *alias*

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an

alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

**TABLESAMPLE** *sampling\_method* ( *argument* [, ...] ) [ REPEATABLE ( *seed* ) ]

A **TABLESAMPLE** clause after a *table\_name* indicates that the specified *sampling\_method* should be used to retrieve a subset of the rows in that table. This sampling precedes the application of any other filters such as **WHERE** clauses. The standard PostgreSQL distribution includes two sampling methods, **BERNOULLI** and **SYSTEM**, and other sampling methods can be installed in the database via extensions.

The **BERNOULLI** and **SYSTEM** sampling methods each accept a single *argument* which is the fraction of the table to sample, expressed as a percentage between 0 and 100. This argument can be any *real*-valued expression. (Other sampling methods might accept more or different arguments.) These two methods each return a randomly-chosen sample of the table that will contain approximately the specified percentage of the table's rows. The **BERNOULLI** method scans the whole table and selects or ignores individual rows independently with the specified probability. The **SYSTEM** method does block-level sampling with each block having the specified chance of being selected; all rows in each selected block are returned. The **SYSTEM** method is significantly faster than the **BERNOULLI** method when small sampling percentages are specified, but it may return a less-random sample of the table as a result of clustering effects.

The optional **REPEATABLE** clause specifies a *seed* number or expression to use for generating random numbers within the sampling method. The seed value can be any non-null floating-point value. Two queries that specify the same seed and *argument* values will select the same sample of the table, if the table has not been changed meanwhile. But different seed values will usually produce different samples. If **REPEATABLE** is not given then a new random sample is selected for each query, based upon a system-generated seed. Note that some add-on sampling methods do not accept **REPEATABLE**, and will always produce new samples on each use.

### *select*

A sub-**SELECT** can appear in the **FROM** clause. This acts as though its output were created as a temporary table for the duration of this single **SELECT** command. Note that the sub-**SELECT** must be surrounded by parentheses, and an alias can be provided in the same way as for a table. A **VALUES** command can also be used here.

### *with\_query\_name*

A **WITH** query is referenced by writing its name, just as though the query's name were a table name. (In fact, the **WITH** query hides any real table of the same name for the purposes of the primary query. If necessary, you can refer to a real table of the same name by schema-qualifying the table's name.) An alias can be provided in the same way as for a table.

### *function\_name*

Function calls can appear in the **FROM** clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though the function's output were created as a temporary table for the duration of this single **SELECT** command. If the function's result type is composite (including the case of a function with multiple **OUT** parameters), each attribute becomes a separate column in the implicit table.

When the optional **WITH ORDINALITY** clause is added to the function call, an additional column of type **bigint** will be appended to the function's result column(s). This column numbers the rows of the function's result set, starting from 1. By default, this column is named **ordinality**.

An alias can be provided in the same way as for a table. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type, including the ordinality column if present.

Multiple function calls can be combined into a single **FROM**-clause item by surrounding them with **ROWS FROM**( ... ). The output of such an item is the concatenation of the first row from each function, then the second row from each function, etc. If some of the functions produce fewer rows than others, null values are substituted for the missing data, so that the total number of rows returned is always the same as for the function that produced the most rows.

If the function has been defined as returning the **record** data type, then an alias or the key word **AS** must be present, followed by a column definition list in the form ( *column\_name data\_type* [, ... ] ). The column definition list must match the actual number and types of columns returned by the function.

When using the **ROWS FROM**( ... ) syntax, if one of the functions requires a column definition list, it's preferred to put the column definition list after the function call inside **ROWS FROM**( ... ). A column definition list can be placed after the **ROWS FROM**( ... ) construct only if there's just a single function and no **WITH ORDINALITY** clause.

To use **ORDINALITY** together with a column definition list, you must use the **ROWS FROM**( ... ) syntax and put the column definition list inside **ROWS FROM**( ... ).

### *join\_type*

One of

- [ **INNER** ] **JOIN**
- **LEFT** [ **OUTER** ] **JOIN**
- **RIGHT** [ **OUTER** ] **JOIN**
- **FULL** [ **OUTER** ] **JOIN**

For the **INNER** and **OUTER** join types, a join condition must be specified, namely exactly one of **ON join\_condition**, **USING (join\_column [, ... ])**, or **NATURAL**. See below for the meaning.

A **JOIN** clause combines two **FROM** items, which for convenience we will refer to as “tables”, though in reality they can be any type of **FROM** item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, **JOINS** nest left-to-right. In any case **JOIN** binds more tightly than the commas separating **FROM**-list items. All the **JOIN** options are just a notational convenience, since they do nothing you couldn't do with plain **FROM** and **WHERE**.

**LEFT OUTER JOIN** returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the **JOIN** clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, **RIGHT OUTER JOIN** returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a **LEFT OUTER JOIN** by switching the left and right tables.

**FULL OUTER JOIN** returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

### **ON join\_condition**

*join\_condition* is an expression resulting in a value of type **boolean** (similar to a **WHERE** clause) that specifies which rows in a join are considered to match.

`USING ( join_column [, ...] ) [ AS join_using_alias ]`

A clause of the form `USING ( a, b, ... )` is shorthand for `ON left_table.a = right_table.a AND left_table.b = right_table.b ...`. Also, `USING` implies that only one of each pair of equivalent columns will be included in the join output, not both.

If a *join\_using\_alias* name is specified, it provides a table alias for the join columns. Only the join columns listed in the `USING` clause are addressable by this name. Unlike a regular *alias*, this does not hide the names of the joined tables from the rest of the query. Also unlike a regular *alias*, you cannot write a column alias list — the output names of the join columns are the same as they appear in the `USING` list.

#### NATURAL

`NATURAL` is shorthand for a `USING` list that mentions all columns in the two tables that have matching names. If there are no common column names, `NATURAL` is equivalent to `ON TRUE`.

#### CROSS JOIN

`CROSS JOIN` is equivalent to `INNER JOIN ON (TRUE)`, that is, no rows are removed by qualification. They produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of `FROM`, but restricted by the join condition (if any).

#### LATERAL

The `LATERAL` key word can precede a sub-`SELECT FROM` item. This allows the sub-`SELECT` to refer to columns of `FROM` items that appear before it in the `FROM` list. (Without `LATERAL`, each sub-`SELECT` is evaluated independently and so cannot cross-reference any other `FROM` item.)

`LATERAL` can also precede a function-call `FROM` item, but in this case it is a noise word, because the function expression can refer to earlier `FROM` items in any case.

A `LATERAL` item can appear at top level in the `FROM` list, or within a `JOIN` tree. In the latter case it can also refer to any items that are on the left-hand side of a `JOIN` that it is on the right-hand side of.

When a `FROM` item contains `LATERAL` cross-references, evaluation proceeds as follows: for each row of the `FROM` item providing the cross-referenced column(s), or set of rows of multiple `FROM` items providing the columns, the `LATERAL` item is evaluated using that row or row set's values of the columns. The resulting row(s) are joined as usual with the rows they were computed from. This is repeated for each row or set of rows from the column source table(s).

The column source table(s) must be `INNER` or `LEFT` joined to the `LATERAL` item, else there would not be a well-defined set of rows from which to compute each set of rows for the `LATERAL` item. Thus, although a construct such as `X RIGHT JOIN LATERAL Y` is syntactically valid, it is not actually allowed for `Y` to reference `X`.

## WHERE Clause

The optional `WHERE` clause has the general form

`WHERE condition`

where *condition* is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

## GROUP BY Clause

The optional `GROUP BY` clause has the general form

`GROUP BY [ ALL | DISTINCT ] grouping_element [, ...]`

`GROUP BY` will condense into a single row all selected rows that share the same values for the grouped expressions. An *expression* used inside a *grouping\_element* can be an input column name, or the name or ordinal number of an output column (`SELECT` list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a `GROUP BY` name will be interpreted as an input-column name rather than an output column name.

If any of `GROUPING SETS`, `ROLLUP` or `CUBE` are present as grouping elements, then the `GROUP BY` clause as a whole defines some number of independent *grouping sets*. The effect of this is equivalent to constructing a `UNION ALL` between subqueries with the individual grouping sets as their `GROUP BY` clauses. The optional `DISTINCT` clause removes duplicate sets before processing; it does *not* transform the `UNION ALL` into a `UNION DISTINCT`. For further details on the handling of grouping sets see Section 7.2.4.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no `GROUP BY` clause, the query is treated as having a single group comprising all the selected rows.) The set of rows fed to each aggregate function can be further filtered by attaching a `FILTER` clause to the aggregate function call; see Section 4.2.7 for more information. When a `FILTER` clause is present, only those rows matching it are included in the input to that aggregate function.

When `GROUP BY` is present, or any aggregate functions are present, it is not valid for the `SELECT` list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any “scalar” expressions in the `HAVING` clause or `SELECT` list. This means that, for example, a `CASE` expression cannot be used to skip evaluation of an aggregate function; see Section 4.2.14.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `GROUP BY`.

## HAVING Clause

The optional `HAVING` clause has the general form

`HAVING condition`

where *condition* is the same as specified for the `WHERE` clause.

`HAVING` eliminates group rows that do not satisfy the condition. `HAVING` is different from `WHERE`: `WHERE` filters individual rows before the application of `GROUP BY`, while `HAVING` filters group rows created by `GROUP BY`. Each column referenced in *condition* must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of `HAVING` turns a query into a grouped query even if there is no `GROUP BY` clause. This is the same as what happens when the query contains aggregate functions but no `GROUP BY` clause. All the selected rows are considered to form a single group, and the `SELECT` list and `HAVING` clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the `HAVING` condition is true, zero rows if it is not true.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `HAVING`.

## WINDOW Clause

The optional WINDOW clause has the general form

```
WINDOW window_name AS ( window_definition ) [, ...]
```

where *window\_name* is a name that can be referenced from OVER clauses or subsequent window definitions, and *window\_definition* is

```
[ existing_window_name ]  
[ PARTITION BY expression [, ...] ]  
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS  
  { FIRST | LAST } ] [, ...] ]  
[ frame_clause ]
```

If an *existing\_window\_name* is specified it must refer to an earlier entry in the WINDOW list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. In this case the new window cannot specify its own PARTITION BY clause, and it can specify ORDER BY only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

The elements of the PARTITION BY list are interpreted in much the same fashion as elements of a GROUP BY clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular GROUP BY clause. They are allowed here because windowing occurs after grouping and aggregation.

Similarly, the elements of the ORDER BY list are interpreted in much the same fashion as elements of a statement-level ORDER BY clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

The optional *frame\_clause* defines the *window frame* for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the *current row*). The *frame\_clause* can be one of

```
{ RANGE | ROWS | GROUPS } frame_start [ frame_exclusion ]  
{ RANGE | ROWS | GROUPS } BETWEEN frame_start AND frame_end  
  [ frame_exclusion ]
```

where *frame\_start* and *frame\_end* can be one of

```
UNBOUNDED PRECEDING  
offset PRECEDING  
CURRENT ROW  
offset FOLLOWING  
UNBOUNDED FOLLOWING
```

and *frame\_exclusion* can be one of

```
EXCLUDE CURRENT ROW  
EXCLUDE GROUP  
EXCLUDE TIES  
EXCLUDE NO OTHERS
```

If *frame\_end* is omitted it defaults to CURRENT ROW. Restrictions are that *frame\_start* cannot be UNBOUNDED FOLLOWING, *frame\_end* cannot be UNBOUNDED PRECEDING, and the

*frame\_end* choice cannot appear earlier in the above list of *frame\_start* and *frame\_end* options than the *frame\_start* choice does — for example `RANGE BETWEEN CURRENT ROW AND offset PRECEDING` is not allowed.

The default framing option is `RANGE UNBOUNDED PRECEDING`, which is the same as `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`; it sets the frame to be all rows from the partition start up through the current row's last *peer* (a row that the window's `ORDER BY` clause considers equivalent to the current row; all rows are peers if there is no `ORDER BY`). In general, `UNBOUNDED PRECEDING` means that the frame starts with the first row of the partition, and similarly `UNBOUNDED FOLLOWING` means that the frame ends with the last row of the partition, regardless of `RANGE`, `ROWS` or `GROUPS` mode. In `ROWS` mode, `CURRENT ROW` means that the frame starts or ends with the current row; but in `RANGE` or `GROUPS` mode it means that the frame starts or ends with the current row's first or last peer in the `ORDER BY` ordering. The *offset* `PRECEDING` and *offset* `FOLLOWING` options vary in meaning depending on the frame mode. In `ROWS` mode, the *offset* is an integer indicating that the frame starts or ends that many rows before or after the current row. In `GROUPS` mode, the *offset* is an integer indicating that the frame starts or ends that many peer groups before or after the current row's peer group, where a *peer group* is a group of rows that are equivalent according to the window's `ORDER BY` clause. In `RANGE` mode, use of an *offset* option requires that there be exactly one `ORDER BY` column in the window definition. Then the frame contains those rows whose ordering column value is no more than *offset* less than (for `PRECEDING`) or more than (for `FOLLOWING`) the current row's ordering column value. In these cases the data type of the *offset* expression depends on the data type of the ordering column. For numeric ordering columns it is typically of the same type as the ordering column, but for datetime ordering columns it is an *interval*. In all these cases, the value of the *offset* must be non-null and non-negative. Also, while the *offset* does not have to be a simple constant, it cannot contain variables, aggregate functions, or window functions.

The *frame\_exclusion* option allows rows around the current row to be excluded from the frame, even if they would be included according to the frame start and frame end options. `EXCLUDE CURRENT ROW` excludes the current row from the frame. `EXCLUDE GROUP` excludes the current row and its ordering peers from the frame. `EXCLUDE TIES` excludes any peers of the current row from the frame, but not the current row itself. `EXCLUDE NO OTHERS` simply specifies explicitly the default behavior of not excluding the current row or its peers.

Beware that the `ROWS` mode can produce unpredictable results if the `ORDER BY` ordering does not order the rows uniquely. The `RANGE` and `GROUPS` modes are designed to ensure that rows that are peers in the `ORDER BY` ordering are treated alike: all rows of a given peer group will be in the frame or excluded from it.

The purpose of a `WINDOW` clause is to specify the behavior of *window functions* appearing in the query's `SELECT` list or `ORDER BY` clause. These functions can reference the `WINDOW` clause entries by name in their `OVER` clauses. A `WINDOW` clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any `WINDOW` clause at all, since a window function call can specify its window definition directly in its `OVER` clause. However, the `WINDOW` clause saves typing when the same window definition is needed for more than one window function.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `WINDOW`.

Window functions are described in detail in Section 3.5, Section 4.2.8, and Section 7.2.5.

## SELECT List

The `SELECT` list (between the key words `SELECT` and `FROM`) specifies expressions that form the output rows of the `SELECT` statement. The expressions can (and usually do) refer to columns computed in the `FROM` clause.

Just as in a table, every output column of a `SELECT` has a name. In a simple `SELECT` this name is just used to label the column for display, but when the `SELECT` is a sub-query of a larger query, the

name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write *AS output\_name* after the column's expression. (You can omit *AS*, but only if the desired output name does not match any PostgreSQL keyword (see Appendix C). For protection against possible future keyword additions, it is recommended that you always either write *AS* or double-quote the output name.) If you do not specify a column name, a name is chosen automatically by PostgreSQL. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases a function or type name may be used, or the system may fall back on a generated name such as `?column?`.

An output column's name can be used to refer to the column's value in *ORDER BY* and *GROUP BY* clauses, but not in the *WHERE* or *HAVING* clauses; there you must write out the expression instead.

Instead of an expression, *\** can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write *table\_name.\** as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with *AS*; the output column names will be the same as the table columns' names.

According to the SQL standard, the expressions in the output list should be computed before applying *DISTINCT*, *ORDER BY*, or *LIMIT*. This is obviously necessary when using *DISTINCT*, since otherwise it's not clear what values are being made distinct. However, in many cases it is convenient if output expressions are computed after *ORDER BY* and *LIMIT*; particularly if the output list contains any volatile or expensive functions. With that behavior, the order of function evaluations is more intuitive and there will not be evaluations corresponding to rows that never appear in the output. PostgreSQL will effectively evaluate output expressions after sorting and limiting, so long as those expressions are not referenced in *DISTINCT*, *ORDER BY* or *GROUP BY*. (As a counterexample, *SELECT f(x) FROM tab ORDER BY 1* clearly must evaluate *f(x)* before sorting.) Output expressions that contain set-returning functions are effectively evaluated after sorting and before limiting, so that *LIMIT* will act to cut off the output from a set-returning function.

### Note

PostgreSQL versions before 9.6 did not provide any guarantees about the timing of evaluation of output expressions versus sorting and limiting; it depended on the form of the chosen query plan.

## DISTINCT Clause

If *SELECT DISTINCT* is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). *SELECT ALL* specifies the opposite: all rows are kept; that is the default.

*SELECT DISTINCT ON ( expression [, ...] )* keeps only the first row of each set of rows where the given expressions evaluate to equal. The *DISTINCT ON* expressions are interpreted using the same rules as for *ORDER BY* (see above). Note that the “first row” of each set is unpredictable unless *ORDER BY* is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
FROM weather_reports
ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used *ORDER BY* to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The *DISTINCT ON* expression(s) must match the leftmost *ORDER BY* expression(s). The *ORDER BY* clause will normally contain additional expression(s) that determine the desired precedence of rows within each *DISTINCT ON* group.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified with DISTINCT.

## UNION Clause

The UNION clause has this general form:

*select\_statement* UNION [ ALL | DISTINCT ] *select\_statement*

*select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, or FOR KEY SHARE clause. (ORDER BY and LIMIT can be attached to a subexpression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the UNION, not to its right-hand input expression.)

The UNION operator computes the set union of the rows returned by the involved SELECT statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two SELECT statements that represent the direct operands of the UNION must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of UNION does not contain any duplicate rows unless the ALL option is specified. ALL prevents elimination of duplicates. (Therefore, UNION ALL is usually significantly quicker than UNION; use ALL when you can.) DISTINCT can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple UNION operators in the same SELECT statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified either for a UNION result or for any input of a UNION.

## INTERSECT Clause

The INTERSECT clause has this general form:

*select\_statement* INTERSECT [ ALL | DISTINCT ] *select\_statement*

*select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, or FOR KEY SHARE clause.

The INTERSECT operator computes the set intersection of the rows returned by the involved SELECT statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of INTERSECT does not contain any duplicate rows unless the ALL option is specified. With ALL, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\min(m,n)$  times in the result set. DISTINCT can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple INTERSECT operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. INTERSECT binds more tightly than UNION. That is, A UNION B INTERSECT C will be read as A UNION (B INTERSECT C).

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified either for an INTERSECT result or for any input of an INTERSECT.

## EXCEPT Clause

The EXCEPT clause has this general form:

*select\_statement* EXCEPT [ ALL | DISTINCT ] *select\_statement*

*select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, or FOR KEY SHARE clause.

The EXCEPT operator computes the set of rows that are in the result of the left SELECT statement but not in the result of the right one.

The result of EXCEPT does not contain any duplicate rows unless the ALL option is specified. With ALL, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\max(m-n, 0)$  times in the result set. DISTINCT can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple EXCEPT operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. EXCEPT binds at the same level as UNION.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified either for an EXCEPT result or for any input of an EXCEPT.

## ORDER BY Clause

The optional ORDER BY clause has this general form:

ORDER BY *expression* [ ASC | DESC | USING *operator* ] [ NULLS { FIRST | LAST } ] [, ...]

The ORDER BY clause causes the result rows to be sorted according to the specified expression(s). If two rows are equal according to the leftmost expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

Each *expression* can be the name or ordinal number of an output column (SELECT list item), or it can be an arbitrary expression formed from input-column values.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to an output column using the AS clause.

It is also possible to use arbitrary expressions in the ORDER BY clause, including columns that do not appear in the SELECT output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an ORDER BY clause applying to the result of a UNION, INTERSECT, or EXCEPT clause can only specify an output column name or number, not an expression.

If an ORDER BY expression is a simple name that matches both an output column name and an input column name, ORDER BY will interpret it as the output column name. This is the opposite of the choice that GROUP BY will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one can add the key word ASC (ascending) or DESC (descending) after any expression in the ORDER BY clause. If not specified, ASC is assumed by default. Alternatively, a specific ordering operator name can be specified in the USING clause. An ordering operator must be a less-than or greater-than member of some B-tree operator family. ASC is usually equivalent to USING < and DESC is usually equivalent to USING >. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If `NULLS LAST` is specified, null values sort after all non-null values; if `NULLS FIRST` is specified, null values sort before all non-null values. If neither is specified, the default behavior is `NULLS LAST` when `ASC` is specified or implied, and `NULLS FIRST` when `DESC` is specified (thus, the default is to act as though nulls are larger than non-nulls). When `USING` is specified, the default nulls ordering depends on whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example `ORDER BY x, y DESC` does not mean the same thing as `ORDER BY x DESC, y DESC`.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden at need by including a `COLLATE` clause in the *expression*, for example `ORDER BY mycolumn COLLATE "en_US"`. For more information see Section 4.2.10 and Section 23.2.

## LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }  
OFFSET start
```

The parameter *count* specifies the maximum number of rows to return, while *start* specifies the number of rows to skip before starting to return rows. When both are specified, *start* rows are skipped before starting to count the *count* rows to be returned.

If the *count* expression evaluates to `NULL`, it is treated as `LIMIT ALL`, i.e., no limit. If *start* evaluates to `NULL`, it is treated the same as `OFFSET 0`.

SQL:2008 introduced a different syntax to achieve the same result, which PostgreSQL also supports. It is:

```
OFFSET start { ROW | ROWS }  
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH  
  TIES }
```

In this syntax, the *start* or *count* value is required by the standard to be a literal constant, a parameter, or a variable name; as a PostgreSQL extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If *count* is omitted in a `FETCH` clause, it defaults to 1. The `WITH TIES` option is used to return any additional rows that tie for the last place in the result set according to the `ORDER BY` clause; `ORDER BY` is mandatory in this case, and `SKIP LOCKED` is not allowed. `ROW` and `ROWS` as well as `FIRST` and `NEXT` are noise words that don't influence the effects of these clauses. According to the standard, the `OFFSET` clause must come before the `FETCH` clause if both are present; but PostgreSQL is laxer and allows either order.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you might be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

The query planner takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result *will give inconsistent results* unless you enforce a predictable result ordering with `ORDER BY`. This is not a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

It is even possible for repeated executions of the same `LIMIT` query to return different subsets of the rows of a table, if there is not an `ORDER BY` to enforce selection of a deterministic subset. Again, this is not a bug; determinism of the results is simply not guaranteed in such a case.

## The Locking Clause

FOR UPDATE, FOR NO KEY UPDATE, FOR SHARE and FOR KEY SHARE are *locking clauses*; they affect how SELECT locks rows as they are obtained from the table.

The locking clause has the general form

```
FOR lock_strength [ OF from_reference [, ...] ] [ NOWAIT | SKIP  
LOCKED ]
```

where *lock\_strength* can be one of

```
UPDATE  
NO KEY UPDATE  
SHARE  
KEY SHARE
```

*from\_reference* must be a table *alias* or non-hidden *table\_name* referenced in the FROM clause. For more information on each row-level lock mode, refer to Section 13.3.2.

To prevent the operation from waiting for other transactions to commit, use either the NOWAIT or SKIP LOCKED option. With NOWAIT, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. With SKIP LOCKED, any selected rows that cannot be immediately locked are skipped. Skipping locked rows provides an inconsistent view of the data, so this is not suitable for general purpose work, but can be used to avoid lock contention with multiple consumers accessing a queue-like table. Note that NOWAIT and SKIP LOCKED apply only to the row-level lock(s) — the required ROW SHARE table-level lock is still taken in the ordinary way (see Chapter 13). You can use LOCK with the NOWAIT option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the SELECT are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to WITH queries referenced by the primary query. If you want row locking to occur within a WITH query, specify a locking clause within the WITH query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as NOWAIT if that is specified in any of the clauses affecting it. Otherwise, it is processed as SKIP LOCKED if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a SELECT query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a LIMIT is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by OFFSET will get locked). Similarly, if a locking clause is used in a cursor's query, only rows actually fetched or stepped past by the cursor will be locked.

When a locking clause appears in a sub-SELECT, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE col1 = 5;
```

will lock only rows having `col1 = 5`, even though that condition is not textually within the sub-query.

Previous releases failed to preserve a lock which is upgraded by a later savepoint. For example, this code:

```
BEGIN;  
SELECT * FROM mytable WHERE key = 1 FOR UPDATE;  
SAVEPOINT s;  
UPDATE mytable SET ... WHERE key = 1;  
ROLLBACK TO s;
```

would fail to preserve the `FOR UPDATE` lock after the `ROLLBACK TO`. This has been fixed in release 9.3.

### Caution

It is possible for a `SELECT` command running at the `READ COMMITTED` transaction isolation level and using `ORDER BY` and a locking clause to return rows out of order. This is because `ORDER BY` is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the `SELECT` unblocks, some of the ordering column values might have been modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the `FOR UPDATE/SHARE` clause in a sub-query, for example

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY  
column1;
```

Note that this will result in locking all rows of `mytable`, whereas `FOR UPDATE` at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the `ORDER BY` is combined with `LIMIT` or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the `REPEATABLE READ` or `SERIALIZABLE` transaction isolation level this would cause a serialization failure (with an `SQLSTATE` of `'40001'`), so there is no possibility of receiving rows out of order under these isolation levels.

## TABLE Command

The command

```
TABLE name
```

is equivalent to

```
SELECT * FROM name
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries. Only the `WITH`, `UNION`, `INTERSECT`, `EXCEPT`, `ORDER BY`, `LIMIT`, `OFFSET`, `FETCH` and `FOR` locking clauses can be used with `TABLE`; the `WHERE` clause and any form of aggregation cannot be used.

## Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind
FROM distributors d JOIN films f USING (did);
```

| title             | did | name         | date_prod  | kind     |
|-------------------|-----|--------------|------------|----------|
| The Third Man     | 101 | British Lion | 1949-12-23 | Drama    |
| The African Queen | 101 | British Lion | 1951-08-11 | Romantic |
| ...               |     |              |            |          |

To sum the column `len` of all films and group the results by `kind`:

```
SELECT kind, sum(len) AS total FROM films GROUP BY kind;
```

| kind     | total |
|----------|-------|
| Action   | 07:34 |
| Comedy   | 02:58 |
| Drama    | 14:28 |
| Musical  | 06:42 |
| Romantic | 04:38 |

To sum the column `len` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```
SELECT kind, sum(len) AS total
FROM films
GROUP BY kind
HAVING sum(len) < interval '5 hours';
```

| kind     | total |
|----------|-------|
| Comedy   | 02:58 |
| Romantic | 04:38 |

The following two examples are identical ways of sorting the individual results according to the contents of the second column (`name`):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

| did | name             |
|-----|------------------|
| 109 | 20th Century Fox |
| 110 | Bavaria Atelier  |
| 101 | British Lion     |
| 107 | Columbia         |
| 102 | Jean Luc Godard  |
| 113 | Luso films       |
| 104 | Mosfilm          |
| 103 | Paramount        |

```
106 | Toho
105 | United Artists
111 | Walt Disney
112 | Warner Bros.
108 | Westward
```

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter W in each table. Only distinct rows are wanted, so the key word `ALL` is omitted.

| distributors: |              | actors: |                |
|---------------|--------------|---------|----------------|
| did           | name         | id      | name           |
| -----         |              | -----   |                |
| 108           | Westward     | 1       | Woody Allen    |
| 111           | Walt Disney  | 2       | Warren Beatty  |
| 112           | Warner Bros. | 3       | Walter Matthau |
| ...           |              | ...     |                |

```
SELECT distributors.name
  FROM distributors
 WHERE distributors.name LIKE 'W%'
UNION
SELECT actors.name
  FROM actors
 WHERE actors.name LIKE 'W%';
```

```
      name
-----
Walt Disney
Walter Matthau
Warner Bros.
Warren Beatty
Westward
Woody Allen
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$
  SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors(111);
 did |   name
-----+-----
 111 | Walt Disney
```

```
CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$
  SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors_2(111) AS (f1 int, f2 text);
 f1 |   f2
-----+-----
 111 | Walt Disney
```

Here is an example of a function with an ordinality column added:

```
SELECT * FROM unnest(ARRAY['a','b','c','d','e','f']) WITH  
ORDINALITY;
```

| unnest | ordinality |
|--------|------------|
| a      | 1          |
| b      | 2          |
| c      | 3          |
| d      | 4          |
| e      | 5          |
| f      | 6          |

(6 rows)

This example shows how to use a simple `WITH` clause:

```
WITH t AS (  
    SELECT random() as x FROM generate_series(1, 3)  
)  
SELECT * FROM t  
UNION ALL  
SELECT * FROM t;  
      x  
-----  
0.534150459803641  
0.520092216785997  
0.0735620250925422  
0.534150459803641  
0.520092216785997  
0.0735620250925422
```

Notice that the `WITH` query was evaluated only once, so that we got two sets of the same three random values.

This example uses `WITH RECURSIVE` to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```
WITH RECURSIVE employee_recursive(distance, employee_name,  
manager_name) AS (  
    SELECT 1, employee_name, manager_name  
    FROM employee  
    WHERE manager_name = 'Mary'  
    UNION ALL  
    SELECT er.distance + 1, e.employee_name, e.manager_name  
    FROM employee_recursive er, employee e  
    WHERE er.employee_name = e.manager_name  
)  
SELECT distance, employee_name FROM employee_recursive;
```

Notice the typical form of recursive queries: an initial condition, followed by `UNION`, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. (See Section 7.8 for more examples.)

This example uses `LATERAL` to apply a set-returning function `get_product_names()` for each row of the `manufacturers` table:

```
SELECT m.name AS mname, pname  
FROM manufacturers m, LATERAL get_product_names(m.id) pname;
```

Manufacturers not currently having any products would not appear in the result, since it is an inner join. If we wished to include the names of such manufacturers in the result, we could do:

```
SELECT m.name AS mname, pname
FROM manufacturers m LEFT JOIN LATERAL get_product_names(m.id)
    pname ON true;
```

## Compatibility

Of course, the `SELECT` statement is compatible with the SQL standard. But there are some extensions and some missing features.

### Omitted FROM Clauses

PostgreSQL allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions:

```
SELECT 2+2;

?column?
-----
      4
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

### Empty SELECT Lists

The list of output expressions after `SELECT` can be empty, producing a zero-column result table. This is not valid syntax according to the SQL standard. PostgreSQL allows it to be consistent with allowing zero-column tables. However, an empty list is not allowed when `DISTINCT` is used.

### Omitting the AS Key Word

In the SQL standard, the optional key word `AS` can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). PostgreSQL is slightly more restrictive: `AS` is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use `AS` or double-quote output column names, to prevent any possible conflict against future keyword additions.

In `FROM` items, both the standard and PostgreSQL allow `AS` to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

### Omitting Sub-SELECT Aliases in FROM

According to the SQL standard, a sub-`SELECT` in the `FROM` list must have an alias. In PostgreSQL, this alias may be omitted.

### ONLY and Inheritance

The SQL standard requires parentheses around the table name when writing `ONLY`, for example `SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE ...`. PostgreSQL considers these parentheses to be optional.

PostgreSQL allows a trailing `*` to be written to explicitly specify the non-`ONLY` behavior of including child tables. The standard does not allow this.

(These points apply equally to all SQL commands supporting the **ONLY** option.)

## **TABLESAMPLE Clause Restrictions**

The **TABLESAMPLE** clause is currently accepted only on regular tables and materialized views. According to the SQL standard it should be possible to apply it to any **FROM** item.

## **Function Calls in FROM**

PostgreSQL allows a function call to be written directly as a member of the **FROM** list. In the SQL standard it would be necessary to wrap such a function call in a sub-**SELECT**; that is, the syntax **FROM func( . . . ) alias** is approximately equivalent to **FROM LATERAL (SELECT func( . . . )) alias**. Note that **LATERAL** is considered to be implicit; this is because the standard requires **LATERAL** semantics for an **UNNEST( )** item in **FROM**. PostgreSQL treats **UNNEST( )** the same as other set-returning functions.

## **Namespace Available to GROUP BY and ORDER BY**

In the SQL-92 standard, an **ORDER BY** clause can only use output column names or numbers, while a **GROUP BY** clause can only use expressions based on input column names. PostgreSQL extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). PostgreSQL also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression will always be taken as input-column names, not as output-column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, PostgreSQL will interpret an **ORDER BY** or **GROUP BY** expression the same way SQL:1999 does.

## **Functional Dependencies**

PostgreSQL recognizes functional dependency (allowing columns to be omitted from **GROUP BY**) only when a table's primary key is included in the **GROUP BY** list. The SQL standard specifies additional conditions that should be recognized.

## **LIMIT and OFFSET**

The clauses **LIMIT** and **OFFSET** are PostgreSQL-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses **OFFSET . . . FETCH {FIRST|NEXT} . . .** for the same functionality, as shown above in **LIMIT** Clause. This syntax is also used by IBM DB2. (Applications written for Oracle frequently use a workaround involving the automatically generated **rownum** column, which is not available in PostgreSQL, to implement the effects of these clauses.)

## **FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, FOR KEY SHARE**

Although **FOR UPDATE** appears in the SQL standard, the standard allows it only as an option of **DECLARE CURSOR**. PostgreSQL allows it in any **SELECT** query as well as in sub-**SELECT**s, but this is an extension. The **FOR NO KEY UPDATE**, **FOR SHARE** and **FOR KEY SHARE** variants, as well as the **NOWAIT** and **SKIP LOCKED** options, do not appear in the standard.

## **Data-Modifying Statements in WITH**

PostgreSQL allows **INSERT**, **UPDATE**, **DELETE**, and **MERGE** to be used as **WITH** queries. This is not found in the SQL standard.

## **Nonstandard Clauses**

**DISTINCT ON ( . . . )** is an extension of the SQL standard.

`ROWS FROM( . . . )` is an extension of the SQL standard.

The `MATERIALIZED` and `NOT MATERIALIZED` options of `WITH` are extensions of the SQL standard.

---

# SELECT INTO

SELECT INTO — define a new table from the results of a query

## Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
    [ { * | expression [ [ AS ] output_name ] } [, ...] ]
    INTO [ TEMPORARY | TEMP | UNLOGGED ] [ TABLE ] new_table
    [ FROM from_item [, ...] ]
    [ WHERE condition ]
    [ GROUP BY expression [, ...] ]
    [ HAVING condition ]
    [ WINDOW window_name AS ( window_definition ) [, ...] ]
    [ { UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] select ]
    [ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS
{ FIRST | LAST } ] [, ...] ]
    [ LIMIT { count | ALL } ]
    [ OFFSET start [ ROW | ROWS ] ]
    [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
    [ FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT ]
[ ... ] ]
```

## Description

SELECT INTO creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal SELECT. The new table's columns have the names and data types associated with the output columns of the SELECT.

## Parameters

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to CREATE TABLE for details.

UNLOGGED

If specified, the table is created as an unlogged table. Refer to CREATE TABLE for details.

*new\_table*

The name (optionally schema-qualified) of the table to be created.

All other parameters are described in detail under SELECT.

## Notes

CREATE TABLE AS is functionally similar to SELECT INTO. CREATE TABLE AS is the recommended syntax, since this form of SELECT INTO is not available in ECPG or PL/pgSQL, because they interpret the INTO clause differently. Furthermore, CREATE TABLE AS offers a superset of the functionality provided by SELECT INTO.

In contrast to CREATE TABLE AS, SELECT INTO does not allow specifying properties like a table's access method with USING *method* or the table's tablespace with TABLESPACE *table-*

*space\_name*. Use `CREATE TABLE AS` if necessary. Therefore, the default table access method is chosen for the new table. See `default_table_access_method` for more information.

## Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
SELECT * INTO films_recent FROM films WHERE date_prod >=
'2002-01-01';
```

## Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. This indeed is the usage found in ECPG (see Chapter 34) and PL/pgSQL (see Chapter 41). The PostgreSQL usage of `SELECT INTO` to represent table creation is historical. Some other SQL implementations also use `SELECT INTO` in this way (but most SQL implementations support `CREATE TABLE AS` instead). Apart from such compatibility considerations, it is best to use `CREATE TABLE AS` for this purpose in new code.

`CREATE TABLE AS`

---

# SET

SET — change a run-time parameter

## Synopsis

```
SET [ SESSION | LOCAL ] configuration_parameter { TO | = } { value  
| 'value' | DEFAULT }  
SET [ SESSION | LOCAL ] TIME ZONE { value | 'value' | LOCAL |  
DEFAULT }
```

## Description

The SET command changes run-time configuration parameters. Many of the run-time parameters listed in Chapter 19 can be changed on-the-fly with SET. (Some parameters can only be changed by superusers and users who have been granted SET privilege on that parameter. There are also parameters that cannot be changed after server or session start.) SET only affects the value used by the current session.

If SET (or equivalently SET SESSION) is issued within a transaction that is later aborted, the effects of the SET command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another SET.

The effects of SET LOCAL last only till the end of the current transaction, whether committed or not. A special case is SET followed by SET LOCAL within a single transaction: the SET LOCAL value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the SET value will take effect.

The effects of SET or SET LOCAL are also canceled by rolling back to a savepoint that is earlier than the command.

If SET LOCAL is used within a function that has a SET option for the same variable (see CREATE FUNCTION), the effects of the SET LOCAL command disappear at function exit; that is, the value in effect when the function was called is restored anyway. This allows SET LOCAL to be used for dynamic or repeated changes of a parameter within a function, while still having the convenience of using the SET option to save and restore the caller's value. However, a regular SET command overrides any surrounding function's SET option; its effects will persist unless rolled back.

### Note

In PostgreSQL versions 8.0 through 8.2, the effects of a SET LOCAL would be canceled by releasing an earlier savepoint, or by successful exit from a PL/pgSQL exception block. This behavior has been changed because it was deemed unintuitive.

## Parameters

### SESSION

Specifies that the command takes effect for the current session. (This is the default if neither SESSION nor LOCAL appears.)

## LOCAL

Specifies that the command takes effect for only the current transaction. After **COMMIT** or **ROLL - BACK**, the session-level setting takes effect again. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

## *configuration\_parameter*

Name of a settable run-time parameter. Available parameters are documented in Chapter 19 and below.

## *value*

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these, as appropriate for the particular parameter. **DEFAULT** can be written to specify resetting the parameter to its default value (that is, whatever value it would have had if no **SET** had been executed in the current session).

Besides the configuration parameters documented in Chapter 19, there are a few that can only be adjusted using the **SET** command or that have a special syntax:

## SCHEMA

**SET SCHEMA 'value'** is an alias for **SET search\_path TO value**. Only one schema can be specified using this syntax.

## NAMES

**SET NAMES 'value'** is an alias for **SET client\_encoding TO value**.

## SEED

Sets the internal seed for the random number generator (the function **random**). Allowed values are floating-point numbers between -1 and 1 inclusive.

The seed can also be set by invoking the function **setseed**:

```
SELECT setseed(value);
```

## TIME ZONE

**SET TIME ZONE 'value'** is an alias for **SET timezone TO 'value'**. The syntax **SET TIME ZONE** allows special syntax for the time zone specification. Here are examples of valid values:

**'America/Los\_Angeles'**

The time zone for Berkeley, California.

**'Europe/Rome'**

The time zone for Italy.

**-7**

The time zone 7 hours west from UTC (equivalent to PDT). Positive values are east from UTC.

**INTERVAL '-08:00' HOUR TO MINUTE**

The time zone 8 hours west from UTC (equivalent to PST).

LOCAL  
DEFAULT

Set the time zone to your local time zone (that is, the server's default value of `timezone`).

Timezone settings given as numbers or intervals are internally translated to POSIX timezone syntax. For example, after `SET TIME ZONE -7`, `SHOW TIME ZONE` would report `<-07>+07`.

Time zone abbreviations are not supported by `SET`; see Section 8.5.3 for more information about time zones.

## Notes

The function `set_config` provides equivalent functionality; see Section 9.28.1. Also, it is possible to `UPDATE` the `pg_settings` system view to perform the equivalent of `SET`.

## Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Set the style of date to traditional POSTGRES with “day before month” input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for Berkeley, California:

```
SET TIME ZONE 'America/Los_Angeles';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

## Compatibility

`SET TIME ZONE` extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while PostgreSQL allows more flexible time-zone specifications. All other `SET` features are PostgreSQL extensions.

# SET CONSTRAINTS

SET CONSTRAINTS — set constraint check timing for the current transaction

## Synopsis

```
SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }
```

## Description

SET CONSTRAINTS sets the behavior of constraint checking within the current transaction. IMMEDIATE constraints are checked at the end of each statement. DEFERRED constraints are not checked until transaction commit. Each constraint has its own IMMEDIATE or DEFERRED mode.

Upon creation, a constraint is given one of three characteristics: DEFERRABLE INITIALLY DEFERRED, DEFERRABLE INITIALLY IMMEDIATE, or NOT DEFERRABLE. The third class is always IMMEDIATE and is not affected by the SET CONSTRAINTS command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by SET CONSTRAINTS.

SET CONSTRAINTS with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. SET CONSTRAINTS ALL changes the mode of all deferrable constraints.

When SET CONSTRAINTS changes the mode of a constraint from DEFERRED to IMMEDIATE, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the SET CONSTRAINTS command. If any such constraint is violated, the SET CONSTRAINTS fails (and does not change the constraint mode). Thus, SET CONSTRAINTS can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only UNIQUE, PRIMARY KEY, REFERENCES (foreign key), and EXCLUDE constraints are affected by this setting. NOT NULL and CHECK constraints are always checked immediately when a row is inserted or modified (*not* at the end of the statement). Uniqueness and exclusion constraints that have not been declared DEFERRABLE are also checked immediately.

The firing of triggers that are declared as “constraint triggers” is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

## Notes

Because PostgreSQL does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case SET CONSTRAINTS will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

## Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in PostgreSQL, it does not apply to NOT NULL and CHECK constraints. Also, PostgreSQL checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.

---

# SET ROLE

SET ROLE — set the current user identifier of the current session

## Synopsis

```
SET [ SESSION | LOCAL ] ROLE role_name
SET [ SESSION | LOCAL ] ROLE NONE
RESET ROLE
```

## Description

This command sets the current user identifier of the current SQL session to be *role\_name*. The role name can be written as either an identifier or a string literal. After SET ROLE, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally. Note that SET ROLE and SET SESSION AUTHORIZATION are exceptions; permissions checks for those continue to use the current session user and the initial session user (the *authenticated user*), respectively.

The current session user must have the SET option for the specified *role\_name*, either directly or indirectly via a chain of memberships with the SET option. (If the session user is a superuser, any role can be selected.)

The SESSION and LOCAL modifiers act the same as for the regular SET command.

SET ROLE NONE sets the current user identifier to the current session user identifier, as returned by session\_user. RESET ROLE sets the current user identifier to the connection-time setting specified by the command-line options, ALTER ROLE, or ALTER DATABASE, if any such settings exist. Otherwise, RESET ROLE sets the current user identifier to the current session user identifier. These forms can be executed by any user.

## Notes

Using this command, it is possible to either add privileges or restrict one's privileges. If the session user role has been granted memberships WITH INHERIT TRUE, it automatically has all the privileges of every such role. In this case, SET ROLE effectively drops all the privileges except for those which the target role directly possesses or inherits. On the other hand, if the session user role has been granted memberships WITH INHERIT FALSE, the privileges of the granted roles can't be accessed by default. However, if the role was granted WITH SET TRUE, the session user can use SET ROLE to drop the privileges assigned directly to the session user and instead acquire the privileges available to the named role. If the role was granted WITH INHERIT FALSE, SET FALSE then the privileges of that role cannot be exercised either with or without SET ROLE.

SET ROLE has effects comparable to SET SESSION AUTHORIZATION, but the privilege checks involved are quite different. Also, SET SESSION AUTHORIZATION determines which roles are allowable for later SET ROLE commands, whereas changing roles with SET ROLE does not change the set of roles allowed to a later SET ROLE.

SET ROLE does not process session variables as specified by the role's ALTER ROLE settings; this only happens during login.

SET ROLE cannot be used within a SECURITY DEFINER function.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;
```

```
  session_user | current_user  
-----+-----  
peter         | peter
```

```
SET ROLE 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
```

```
  session_user | current_user  
-----+-----  
peter         | paul
```

## Compatibility

PostgreSQL allows identifier syntax ("*rolename*"), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; PostgreSQL does not make this restriction because there is no reason to. The **SESSION** and **LOCAL** modifiers are a PostgreSQL extension, as is the **RESET** syntax.

## See Also

SET SESSION AUTHORIZATION

---

# SET SESSION AUTHORIZATION

SET SESSION AUTHORIZATION — set the session user identifier and the current user identifier of the current session

## Synopsis

```
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION user_name
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

## Description

This command sets the session user identifier and the current user identifier of the current SQL session to be *user\_name*. The user name can be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session user identifier is initially set to be the (possibly authenticated) user name provided by the client. The current user identifier is normally equal to the session user identifier, but might change temporarily in the context of SECURITY DEFINER functions and similar mechanisms; it can also be changed by SET ROLE. The current user identifier is relevant for permission checking.

The session user identifier can be changed only if the initial session user (the *authenticated user*) has the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The SESSION and LOCAL modifiers act the same as for the regular SET command.

The DEFAULT and RESET forms reset the session and current user identifiers to be the originally authenticated user name. These forms can be executed by any user.

## Notes

SET SESSION AUTHORIZATION cannot be used within a SECURITY DEFINER function.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;

 session_user | current_user 
-----+-----
peter        | peter

SET SESSION AUTHORIZATION 'paul';

SELECT SESSION_USER, CURRENT_USER;

 session_user | current_user 
-----+-----
paul         | paul
```

## Compatibility

The SQL standard allows some other expressions to appear in place of the literal *user\_name*, but these options are not important in practice. PostgreSQL allows identifier syntax ("*username*"), which SQL does not. SQL does not allow this command during a transaction; PostgreSQL does not make this restriction because there is no reason to. The **SESSION** and **LOCAL** modifiers are a PostgreSQL extension, as is the **RESET** syntax.

The privileges necessary to execute this command are left implementation-defined by the standard.

SET ROLE

---

# SET TRANSACTION

SET TRANSACTION — set the characteristics of the current transaction

## Synopsis

```
SET TRANSACTION transaction_mode [, ...]
SET TRANSACTION SNAPSHOT snapshot_id
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode [, ...]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ
COMMITTED | READ UNCOMMITTED }
READ WRITE | READ ONLY
[ NOT ] DEFERRABLE
```

## Description

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions. `SET SESSION CHARACTERISTICS` sets the default transaction characteristics for subsequent transactions of a session. These defaults can be overridden by `SET TRANSACTION` for an individual transaction.

The available transaction characteristics are the transaction isolation level, the transaction access mode (read/write or read-only), and the deferrable mode. In addition, a snapshot can be selected, though only for the current transaction, not as a session default.

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently:

### READ COMMITTED

A statement can only see rows committed before it began. This is the default.

### REPEATABLE READ

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction.

### SERIALIZABLE

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction. If a pattern of reads and writes among concurrent serializable transactions would create a situation which could not have occurred for any serial (one-at-a-time) execution of those transactions, one of them will be rolled back with a `serialization_failure` error.

The SQL standard defines one additional level, `READ UNCOMMITTED`. In PostgreSQL `READ UNCOMMITTED` is treated as `READ COMMITTED`.

The transaction isolation level cannot be changed after the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `MERGE`, `FETCH`, or `COPY`) of a transaction has been executed. See Chapter 13 for more information about transaction isolation and concurrency control.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`,

UPDATE, DELETE, MERGE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; COMMENT, GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The DEFERRABLE transaction property has no effect unless the transaction is also SERIALIZABLE and READ ONLY. When all three of these properties are selected for a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a SERIALIZABLE transaction and without any risk of contributing to or being canceled by a serialization failure. This mode is well suited for long-running reports or backups.

The SET TRANSACTION SNAPSHOT command allows a new transaction to run with the same *snapshot* as an existing transaction. The pre-existing transaction must have exported its snapshot with the pg\_export\_snapshot function (see Section 9.28.5). That function returns a snapshot identifier, which must be given to SET TRANSACTION SNAPSHOT to specify which snapshot is to be imported. The identifier must be written as a string literal in this command, for example '00000003-0000001B-1'. SET TRANSACTION SNAPSHOT can only be executed at the start of a transaction, before the first query or data-modification statement (SELECT, INSERT, DELETE, UPDATE, MERGE, FETCH, or COPY) of the transaction. Furthermore, the transaction must already be set to SERIALIZABLE or REPEATABLE READ isolation level (otherwise, the snapshot would be discarded immediately, since READ COMMITTED mode takes a new snapshot for each command). If the importing transaction uses SERIALIZABLE isolation level, then the transaction that exported the snapshot must also use that isolation level. Also, a non-read-only serializable transaction cannot import a snapshot from a read-only transaction.

## Notes

If SET TRANSACTION is executed without a prior START TRANSACTION or BEGIN, it emits a warning and otherwise has no effect.

It is possible to dispense with SET TRANSACTION by instead specifying the desired *transaction\_modes* in BEGIN or START TRANSACTION. But that option is not available for SET TRANSACTION SNAPSHOT.

The session default transaction modes can also be set or examined via the configuration parameters default\_transaction\_isolation, default\_transaction\_read\_only, and default\_transaction\_deferrable. (In fact SET SESSION CHARACTERISTICS is just a verbose equivalent for setting these variables with SET.) This means the defaults can be set in the configuration file, via ALTER DATABASE, etc. Consult Chapter 19 for more information.

The current transaction's modes can similarly be set or examined via the configuration parameters transaction\_isolation, transaction\_read\_only, and transaction\_deferrable. Setting one of these parameters acts the same as the corresponding SET TRANSACTION option, with the same restrictions on when it can be done. However, these parameters cannot be set in the configuration file, or from any source other than live SQL.

## Examples

To begin a new transaction with the same snapshot as an already existing transaction, first export the snapshot from the existing transaction. That will return the snapshot identifier, for example:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SELECT pg_export_snapshot();
       pg_export_snapshot
-----
00000003-0000001B-1
(1 row)
```

Then give the snapshot identifier in a `SET TRANSACTION SNAPSHOT` command at the beginning of the newly opened transaction:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;  
SET TRANSACTION SNAPSHOT '00000003-0000001B-1';
```

## Compatibility

These commands are defined in the SQL standard, except for the `DEFERRABLE` transaction mode and the `SET TRANSACTION SNAPSHOT` form, which are PostgreSQL extensions.

`SERIALIZABLE` is the default transaction isolation level in the standard. In PostgreSQL the default is ordinarily `READ COMMITTED`, but you can change it as mentioned above.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the PostgreSQL server.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons PostgreSQL allows the commas to be omitted.

---

# SHOW

SHOW — show the value of a run-time parameter

## Synopsis

```
SHOW name
SHOW ALL
```

## Description

SHOW will display the current setting of run-time parameters. These variables can be set using the SET statement, by editing the `postgresql.conf` configuration file, through the `PGOPTIONS` environmental variable (when using libpq or a libpq-based application), or through command-line flags when starting the `postgres` server. See Chapter 19 for details.

## Parameters

*name*

The name of a run-time parameter. Available parameters are documented in Chapter 19 and on the SET reference page. In addition, there are a few parameters that can be shown but not set:

SERVER\_VERSION

Shows the server's version number.

SERVER\_ENCODING

Shows the server-side character set encoding. At present, this parameter can be shown but not set, because the encoding is determined at database creation time.

IS\_SUPERUSER

True if the current role has superuser privileges.

ALL

Show the values of all configuration parameters, with descriptions.

## Notes

The function `current_setting` produces equivalent output; see Section 9.28.1. Also, the `pg_settings` system view produces the same information.

## Examples

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
DateStyle
-----
ISO, MDY
(1 row)
```

Show the current setting of the parameter `geqo`:

```
SHOW geqo;
geqo
-----
on
(1 row)
```

Show all settings:

```
SHOW ALL;
          name          | setting | description
-----+-----
allow_system_table_mods | off     | Allows modifications of the
structure of ...
.
.
.
xmloption                | content | Sets whether XML data in
implicit parsing ...
zero_damaged_pages       | off     | Continues processing past
damaged page headers.
(196 rows)
```

## Compatibility

The `SHOW` command is a PostgreSQL extension.

## See Also

SET, RESET

---

# START TRANSACTION

START TRANSACTION — start a transaction block

## Synopsis

```
START TRANSACTION [ transaction_mode [, ...] ]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ  
COMMITTED | READ UNCOMMITTED }  
READ WRITE | READ ONLY  
[ NOT ] DEFERRABLE
```

## Description

This command begins a new transaction block. If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was executed. This is the same as the BEGIN command.

## Parameters

Refer to SET TRANSACTION for information on the meaning of the parameters to this statement.

## Compatibility

In the standard, it is not necessary to issue START TRANSACTION to start a transaction block: any SQL command implicitly begins a block. PostgreSQL's behavior can be seen as implicitly issuing a COMMIT after each command that does not follow START TRANSACTION (or BEGIN), and it is therefore often called “autocommit”. Other relational database systems might offer an autocommit feature as a convenience.

The DEFERRABLE *transaction\_mode* is a PostgreSQL language extension.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons PostgreSQL allows the commas to be omitted.

See also the compatibility section of SET TRANSACTION.

# TRUNCATE

TRUNCATE — empty a table or set of tables

## Synopsis

```
TRUNCATE [ TABLE ] [ ONLY ] name [ * ] [, ... ]  
        [ RESTART IDENTITY | CONTINUE IDENTITY ] [ CASCADE | RESTRICT ]
```

## Description

TRUNCATE quickly removes all rows from a set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. Furthermore, it reclaims disk space immediately, rather than requiring a subsequent VACUUM operation. This is most useful on large tables.

## Parameters

*name*

The name (optionally schema-qualified) of a table to truncate. If ONLY is specified before the table name, only that table is truncated. If ONLY is not specified, the table and all its descendant tables (if any) are truncated. Optionally, \* can be specified after the table name to explicitly indicate that descendant tables are included.

RESTART IDENTITY

Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY

Do not change the values of sequences. This is the default.

CASCADE

Automatically truncate all tables that have foreign-key references to any of the named tables, or to any tables added to the group due to CASCADE.

RESTRICT

Refuse to truncate if any of the tables have foreign-key references from tables that are not listed in the command. This is the default.

## Notes

You must have the TRUNCATE privilege on a table to truncate it.

TRUNCATE acquires an ACCESS EXCLUSIVE lock on each table it operates on, which blocks all other concurrent operations on the table. When RESTART IDENTITY is specified, any sequences that are to be restarted are likewise locked exclusively. If concurrent access to a table is required, then the DELETE command should be used instead.

TRUNCATE cannot be used on a table that has foreign-key references from other tables, unless all such tables are also truncated in the same command. Checking validity in such cases would require table scans, and the whole point is not to do one. The CASCADE option can be used to automatically include

all dependent tables — but be very careful when using this option, or else you might lose data you did not intend to! Note in particular that when the table to be truncated is a partition, siblings partitions are left untouched, but cascading occurs to all referencing tables and all their partitions with no distinction.

TRUNCATE will not fire any **ON DELETE** triggers that might exist for the tables. But it will fire **ON TRUNCATE** triggers. If **ON TRUNCATE** triggers are defined for any of the tables, then all **BEFORE TRUNCATE** triggers are fired before any truncation happens, and all **AFTER TRUNCATE** triggers are fired after the last truncation is performed and any sequences are reset. The triggers will fire in the order that the tables are to be processed (first those listed in the command, and then any that were added due to cascading).

TRUNCATE is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred. See Section 13.6 for more details.

TRUNCATE is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.

When **RESTART IDENTITY** is specified, the implied **ALTER SEQUENCE RESTART** operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back, but not their effects on `currval()`; that is, after the transaction `currval()` will continue to reflect the last sequence value obtained inside the failed transaction, even though the sequence itself may no longer be consistent with that. This is similar to the usual behavior of `currval()` after a failed transaction.

TRUNCATE can be used for foreign tables if supported by the foreign data wrapper, for instance, see `postgres_fdw`.

## Examples

Truncate the tables `bigtable` and `fattable`:

```
TRUNCATE bigtable, fattable;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE bigtable, fattable RESTART IDENTITY;
```

Truncate the table `othertable`, and cascade to any tables that reference `othertable` via foreign-key constraints:

```
TRUNCATE othertable CASCADE;
```

## Compatibility

The SQL:2008 standard includes a TRUNCATE command with the syntax **TRUNCATE TABLE *tablename***. The clauses **CONTINUE IDENTITY/RESTART IDENTITY** also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

DELETE

---

# UNLISTEN

UNLISTEN — stop listening for a notification

## Synopsis

```
UNLISTEN { channel | * }
```

## Description

UNLISTEN is used to remove an existing registration for NOTIFY events. UNLISTEN cancels any existing registration of the current PostgreSQL session as a listener on the notification channel named *channel*. The special wildcard *\** cancels all listener registrations for the current session.

NOTIFY contains a more extensive discussion of the use of LISTEN and NOTIFY.

## Parameters

*channel*

Name of a notification channel (any identifier).

*\**

All current listen registrations for this session are cleared.

## Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, UNLISTEN *\** is automatically executed.

A transaction that has executed UNLISTEN cannot be prepared for two-phase commit.

## Examples

To make a registration:

```
LISTEN virtual;  
NOTIFY virtual;  
Asynchronous notification "virtual" received from server process  
with PID 8448.
```

Once UNLISTEN has been executed, further NOTIFY messages will be ignored:

```
UNLISTEN virtual;  
NOTIFY virtual;  
-- no NOTIFY event is received
```

## Compatibility

There is no UNLISTEN command in the SQL standard.

## See Also

LISTEN, NOTIFY

---

# UPDATE

UPDATE — update rows of a table

## Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [ ONLY ] table_name [ * ] [ [ AS ] alias ]
    SET { column_name = { expression | DEFAULT } |
        ( column_name [, ...] ) = [ ROW ] ( { expression |
DEFAULT } [, ...] ) |
        ( column_name [, ...] ) = ( sub-SELECT )
    } [, ...]
    [ FROM from_item [, ...] ]
    [ WHERE condition | WHERE CURRENT OF cursor_name ]
    [ RETURNING [ WITH ( { OLD | NEW } AS output_alias [, ...] ) ]
        { * | output_expression [ [ AS ] output_name ] }
    ]
[, ...] ]
```

## Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes UPDATE to compute and return value(s) based on each row actually updated. Any expression using the table's columns, and/or columns of other tables mentioned in FROM, can be computed. By default, the new (post-update) values of the table's columns are used, but it is also possible to request the old (pre-update) values. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the UPDATE privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the SELECT privilege on any column whose values are read in the *expressions* or *condition*.

## Parameters

*with\_query*

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the UPDATE query. See Section 7.8 and SELECT for details.

*table\_name*

The name (optionally schema-qualified) of the table to update. If ONLY is specified before the table name, matching rows are updated in the named table only. If ONLY is not specified, matching rows are also updated in any tables inheriting from the named table. Optionally, \* can be specified after the table name to explicitly indicate that descendant tables are included.

*alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the `UPDATE` statement must refer to this table as `f` not `foo`.

*column\_name*

The name of a column in the table named by *table\_name*. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column — for example, `UPDATE table_name SET table_name.col = 1` is invalid.

*expression*

An expression to assign to the column. The expression can use the old values of this and other columns in the table.

## DEFAULT

Set the column to its default value (which will be `NULL` if no specific default expression has been assigned to it). An identity column will be set to a new value generated by the associated sequence. For a generated column, specifying this is permitted but merely specifies the normal behavior of computing the column from its generation expression.

*sub-SELECT*

A `SELECT` sub-query that produces as many output columns as are listed in the parenthesized column list preceding it. The sub-query must yield no more than one row when executed. If it yields one row, its column values are assigned to the target columns; if it yields no rows, `NULL` values are assigned to the target columns. The sub-query can refer to old values of the current row of the table being updated.

*from\_item*

A table expression allowing columns from other tables to appear in the `WHERE` condition and update expressions. This uses the same syntax as the `FROM` clause of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table as a *from\_item* unless you intend a self-join (in which case it must appear with an alias in the *from\_item*).

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated.

*cursor\_name*

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be updated is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the `UPDATE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See `DECLARE` for more information about using cursors with `WHERE CURRENT OF`.

*output\_alias*

An optional substitute name for `OLD` or `NEW` rows in the `RETURNING` list.

By default, old values from the target table can be returned by writing `OLD.column_name` or `OLD.*`, and new values can be returned by writing `NEW.column_name` or `NEW.*`. When an alias is provided, these names are hidden and the old or new rows must be referred to using the alias. For example `RETURNING WITH (OLD AS o, NEW AS n) o.*, n.*`.

*output\_expression*

An expression to be computed and returned by the **UPDATE** command after each row is updated. The expression can use any column names of the table named by *table\_name* or table(s) listed in **FROM**. Write **\*** to return all columns.

A column name or **\*** may be qualified using **OLD** or **NEW**, or the corresponding *output\_alias* for **OLD** or **NEW**, to cause old or new values to be returned. An unqualified column name, or **\***, or a column name or **\*** qualified using the target table name or alias will return new values.

*output\_name*

A name to use for a returned column.

## Outputs

On successful completion, an **UPDATE** command returns a command tag of the form

**UPDATE** *count*

The *count* is the number of rows updated, including matched rows whose values did not change. Note that the number may be less than the number of rows that matched the *condition* when updates were suppressed by a **BEFORE UPDATE** trigger. If *count* is 0, no rows were updated by the query (this is not considered an error).

If the **UPDATE** command contains a **RETURNING** clause, the result will be similar to that of a **SELECT** statement containing the columns and values defined in the **RETURNING** list, computed over the row(s) updated by the command.

## Notes

When a **FROM** clause is present, what essentially happens is that the target table is joined to the tables mentioned in the *from\_item* list, and each output row of the join represents an update operation for the target table. When using **FROM** you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row shouldn't join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

In the case of a partitioned table, updating a row might cause it to no longer satisfy the partition constraint of the containing partition. In that case, if there is some other partition in the partition tree for which this row satisfies its partition constraint, then the row is moved to that partition. If there is no such partition, an error will occur. Behind the scenes, the row movement is actually a **DELETE** and **INSERT** operation.

There is a possibility that a concurrent **UPDATE** or **DELETE** on the row being moved will get a serialization failure error. Suppose session 1 is performing an **UPDATE** on a partition key, and meanwhile a concurrent session 2 for which this row is visible performs an **UPDATE** or **DELETE** operation on this row. In such case, session 2's **UPDATE** or **DELETE** will detect the row movement and raise a serialization failure error (which always returns with an SQLSTATE code '40001'). Applications may wish to retry the transaction if this occurs. In the usual case where the table is not partitioned, or where there is no row movement, session 2 would have identified the newly updated row and carried out the **UPDATE/DELETE** on this new row version.

Note that while rows can be moved from local partitions to a foreign-table partition (provided the foreign data wrapper supports tuple routing), they cannot be moved from a foreign-table partition to another partition.

An attempt of moving a row from one partition to another will fail if a foreign key is found to directly reference an ancestor of the source partition that is not the same as the ancestor that's mentioned in the UPDATE query.

## Examples

Change the word Drama to Dramatic in the column kind of the table films:

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table weather:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp
= DEFAULT
WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Perform the same operation and return the updated entries, and the old precipitation value:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp
= DEFAULT
WHERE city = 'San Francisco' AND date = '2003-07-03'
RETURNING temp_lo, temp_hi, prcp, old.prcp AS old_prcp;
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo
+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the FROM clause syntax:

```
UPDATE employees SET sales_count = sales_count + 1 FROM accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.sales_person;
```

Perform the same operation, using a sub-select in the WHERE clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
(SELECT sales_person FROM accounts WHERE name = 'Acme
Corporation');
```

Update contact names in an accounts table to match the currently assigned salespeople:

```
UPDATE accounts SET (contact_first_name, contact_last_name) =
(SELECT first_name, last_name FROM employees
WHERE employees.id = accounts.sales_person);
```

A similar result could be accomplished with a join:

```
UPDATE accounts SET contact_first_name = first_name,
contact_last_name = last_name
```

```
FROM employees WHERE employees.id = accounts.sales_person;
```

However, the second query may give unexpected results if `employees.id` is not a unique key, whereas the first query is guaranteed to raise an error if there are multiple `id` matches. Also, if there is no match for a particular `accounts.sales_person` entry, the first query will set the corresponding name fields to `NULL`, whereas the second query will not update that row at all.

Update statistics in a summary table to match the current data:

```
UPDATE summary s SET (sum_x, sum_y, avg_x, avg_y) =
    (SELECT sum(x), sum(y), avg(x), avg(y) FROM data d
     WHERE d.group_id = s.group_id);
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use save-points:

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau
    Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

Change the `kind` column of the table `films` in the row on which the cursor `c_films` is currently positioned:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

Updates affecting many rows can have negative effects on system performance, such as table bloat, increased replica lag, and increased lock contention. In such situations it can make sense to perform the operation in smaller batches, possibly with a `VACUUM` operation on the table between batches. While there is no `LIMIT` clause for `UPDATE`, it is possible to get a similar effect through the use of a Common Table Expression and a self-join. With the standard PostgreSQL table access method, a self-join on the system column `ctid` is very efficient:

```
WITH exceeded_max_retries AS (
    SELECT w.ctid FROM work_item AS w
    WHERE w.status = 'active' AND w.num_retries > 10
    ORDER BY w.retry_timestamp
    FOR UPDATE
    LIMIT 5000
)
UPDATE work_item SET status = 'failed'
FROM exceeded_max_retries AS emr
WHERE work_item.ctid = emr.ctid;
```

This command will need to be repeated until no rows remain to be updated. (This use of `ctid` is only safe because the query is repeatedly run, avoiding the problem of changed `ctids`.) Use of an `ORDER BY` clause allows the command to prioritize which rows will be updated; it can also prevent deadlock with other update operations if they use the same ordering. If lock contention is a concern,

then `SKIP LOCKED` can be added to the CTE to prevent multiple commands from updating the same row. However, then a final `UPDATE` without `SKIP LOCKED` or `LIMIT` will be needed to ensure that no matching rows were overlooked.

## Compatibility

This command conforms to the SQL standard, except that the `FROM` and `RETURNING` clauses are PostgreSQL extensions, as is the ability to use `WITH` with `UPDATE`.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how PostgreSQL interprets `FROM`. Be careful when porting applications that use this extension.

According to the standard, the source value for a parenthesized sub-list of target column names can be any row-valued expression yielding the correct number of columns. PostgreSQL only allows the source value to be a row constructor or a sub-`SELECT`. An individual column's updated value can be specified as `DEFAULT` in the row-constructor case, but not inside a sub-`SELECT`.

---

# VACUUM

VACUUM — garbage-collect and optionally analyze a database

## Synopsis

```
VACUUM [ ( option [, ...] ) ] [ table_and_columns [, ...] ]
```

where *option* can be one of:

```
FULL [ boolean ]
FREEZE [ boolean ]
VERBOSE [ boolean ]
ANALYZE [ boolean ]
DISABLE_PAGE_SKIPPING [ boolean ]
SKIP_LOCKED [ boolean ]
INDEX_CLEANUP { AUTO | ON | OFF }
PROCESS_MAIN [ boolean ]
PROCESS_TOAST [ boolean ]
TRUNCATE [ boolean ]
PARALLEL integer
SKIP_DATABASE_STATS [ boolean ]
ONLY_DATABASE_STATS [ boolean ]
BUFFER_USAGE_LIMIT size
```

and *table\_and\_columns* is:

```
[ ONLY ] table_name [ * ] [ ( column_name [, ...] ) ]
```

## Description

VACUUM reclaims storage occupied by dead tuples. In normal PostgreSQL operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present until a VACUUM is done. Therefore it's necessary to do VACUUM periodically, especially on frequently-updated tables.

Without a *table\_and\_columns* list, VACUUM processes every table and materialized view in the current database that the current user has permission to vacuum. With a list, VACUUM processes only those table(s).

VACUUM ANALYZE performs a VACUUM and then an ANALYZE for each selected table. This is a handy combination form for routine maintenance scripts. See ANALYZE for more details about its processing.

Plain VACUUM (without FULL) simply reclaims space and makes it available for re-use. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it's just kept available for re-use within the same table. It also allows us to leverage multiple CPUs in order to process indexes. This feature is known as *parallel vacuum*. To disable this feature, one can use PARALLEL option and specify parallel workers as zero. VACUUM FULL rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an ACCESS EXCLUSIVE lock on each table while it is being processed.

## Parameters

### FULL

Selects “full” vacuum, which can reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and doesn't release the old copy until the operation is complete. Usually this should only be used when a significant amount of space needs to be reclaimed from within the table.

### FREEZE

Selects aggressive “freezing” of tuples. Specifying **FREEZE** is equivalent to performing **VACUUM** with the `vacuum_freeze_min_age` and `vacuum_freeze_table_age` parameters set to zero. Aggressive freezing is always performed when the table is rewritten, so this option is redundant when **FULL** is specified.

### VERBOSE

Prints a detailed vacuum activity report for each table at **INFO** level.

### ANALYZE

Updates statistics used by the planner to determine the most efficient way to execute a query.

### DISABLE\_PAGE\_SKIPPING

Normally, **VACUUM** will skip pages based on the visibility map. Pages where all tuples are known to be frozen can always be skipped, and those where all tuples are known to be visible to all transactions may be skipped except when performing an aggressive vacuum. Furthermore, except when performing an aggressive vacuum, some pages may be skipped in order to avoid waiting for other sessions to finish using them. This option disables all page-skipping behavior, and is intended to be used only when the contents of the visibility map are suspect, which should happen only if there is a hardware or software issue causing database corruption.

### SKIP\_LOCKED

Specifies that **VACUUM** should not wait for any conflicting locks to be released when beginning work on a relation: if a relation cannot be locked immediately without waiting, the relation is skipped. Note that even with this option, **VACUUM** may still block when opening the relation's indexes. Additionally, **VACUUM ANALYZE** may still block when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while **VACUUM** ordinarily processes all partitions of specified partitioned tables, this option will cause **VACUUM** to skip all partitions if there is a conflicting lock on the partitioned table.

### INDEX\_CLEANUP

Normally, **VACUUM** will skip index vacuuming when there are very few dead tuples in the table. The cost of processing all of the table's indexes is expected to greatly exceed the benefit of removing dead index tuples when this happens. This option can be used to force **VACUUM** to process indexes when there are more than zero dead tuples. The default is **AUTO**, which allows **VACUUM** to skip index vacuuming when appropriate. If **INDEX\_CLEANUP** is set to **ON**, **VACUUM** will conservatively remove all dead tuples from indexes. This may be useful for backwards compatibility with earlier releases of PostgreSQL where this was the standard behavior.

**INDEX\_CLEANUP** can also be set to **OFF** to force **VACUUM** to *always* skip index vacuuming, even when there are many dead tuples in the table. This may be useful when it is necessary to make **VACUUM** run as quickly as possible to avoid imminent transaction ID wraparound (see Section 24.1.5). However, the wraparound failsafe mechanism controlled by `vacuum_failsafe_age` will generally trigger automatically to avoid transaction ID wraparound failure, and should be preferred. If index cleanup is not performed regularly, performance may suffer, because as the

table is modified indexes will accumulate dead tuples and the table itself will accumulate dead line pointers that cannot be removed until index cleanup is completed.

This option has no effect for tables that have no index and is ignored if the **FULL** option is used. It also has no effect on the transaction ID wraparound failsafe mechanism. When triggered it will skip index vacuuming, even when **INDEX\_CLEANUP** is set to **ON**.

#### PROCESS\_MAIN

Specifies that **VACUUM** should attempt to process the main relation. This is usually the desired behavior and is the default. Setting this option to false may be useful when it is only necessary to vacuum a relation's corresponding **TOAST** table.

#### PROCESS\_TOAST

Specifies that **VACUUM** should attempt to process the corresponding **TOAST** table for each relation, if one exists. This is usually the desired behavior and is the default. Setting this option to false may be useful when it is only necessary to vacuum the main relation. This option is required when the **FULL** option is used.

#### TRUNCATE

Specifies that **VACUUM** should attempt to truncate off any empty pages at the end of the table and allow the disk space for the truncated pages to be returned to the operating system. This is normally the desired behavior and is the default unless `vacuum_truncate` is set to false or the `vacuum_truncate` option has been set to false for the table to be vacuumed. Setting this option to false may be useful to avoid **ACCESS EXCLUSIVE** lock on the table that the truncation requires. This option is ignored if the **FULL** option is used.

#### PARALLEL

Perform index vacuum and index cleanup phases of **VACUUM** in parallel using *integer* background workers (for the details of each vacuum phase, please refer to Table 27.46). The number of workers used to perform the operation is equal to the number of indexes on the relation that support parallel vacuum which is limited by the number of workers specified with **PARALLEL** option if any which is further limited by `max_parallel_maintenance_workers`. An index can participate in parallel vacuum if and only if the size of the index is more than `min_parallel_index_scan_size`. Please note that it is not guaranteed that the number of parallel workers specified in *integer* will be used during execution. It is possible for a vacuum to run with fewer workers than specified, or even with no workers at all. Only one worker can be used per index. So parallel workers are launched only when there are at least 2 indexes in the table. Workers for vacuum are launched before the start of each phase and exit at the end of the phase. These behaviors might change in a future release. This option can't be used with the **FULL** option.

#### SKIP\_DATABASE\_STATS

Specifies that **VACUUM** should skip updating the database-wide statistics about oldest unfrozen XIDs. Normally **VACUUM** will update these statistics once at the end of the command. However, this can take awhile in a database with a very large number of tables, and it will accomplish nothing unless the table that had contained the oldest unfrozen XID was among those vacuumed. Moreover, if multiple **VACUUM** commands are issued in parallel, only one of them can update the database-wide statistics at a time. Therefore, if an application intends to issue a series of many **VACUUM** commands, it can be helpful to set this option in all but the last such command; or set it in all the commands and separately issue **VACUUM (ONLY\_DATABASE\_STATS)** afterwards.

#### ONLY\_DATABASE\_STATS

Specifies that **VACUUM** should do nothing except update the database-wide statistics about oldest unfrozen XIDs. When this option is specified, the *table\_and\_columns* list must be empty, and no other option may be enabled except **VERBOSE**.

**BUFFER\_USAGE\_LIMIT**

Specifies the *Buffer Access Strategy* ring buffer size for **VACUUM**. This size is used to calculate the number of shared buffers which will be reused as part of this strategy. 0 disables use of a *Buffer Access Strategy*. If **ANALYZE** is also specified, the **BUFFER\_USAGE\_LIMIT** value is used for both the vacuum and analyze stages. This option can't be used with the **FULL** option except if **ANALYZE** is also specified. When this option is not specified, **VACUUM** uses the value from `vacuum_buffer_usage_limit`. Higher settings can allow **VACUUM** to run more quickly, but having too large a setting may cause too many other useful pages to be evicted from shared buffers. The minimum value is 128 kB and the maximum value is 16 GB.

*boolean*

Specifies whether the selected option should be turned on or off. You can write **TRUE**, **ON**, or 1 to enable the option, and **FALSE**, **OFF**, or 0 to disable it. The *boolean* value can also be omitted, in which case **TRUE** is assumed.

*integer*

Specifies a non-negative integer value passed to the selected option.

*size*

Specifies an amount of memory in kilobytes. Sizes may also be specified as a string containing the numerical size followed by any one of the following memory units: B (bytes), kB (kilobytes), MB (megabytes), GB (gigabytes), or TB (terabytes).

*table\_name*

The name (optionally schema-qualified) of a specific table or materialized view to vacuum. If **ONLY** is specified before the table name, only that table is vacuumed. If **ONLY** is not specified, the table and all its inheritance child tables or partitions (if any) are also vacuumed. Optionally, **\*** can be specified after the table name to explicitly indicate that inheritance child tables (or partitions) are to be vacuumed.

*column\_name*

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, **ANALYZE** must also be specified.

## Outputs

When **VERBOSE** is specified, **VACUUM** emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

## Notes

To vacuum a table, one must ordinarily have the **MAINTAIN** privilege on the table. However, database owners are allowed to vacuum all tables in their databases, except shared catalogs. **VACUUM** will skip over any tables that the calling user does not have permission to vacuum.

While **VACUUM** is running, the `search_path` is temporarily changed to `pg_catalog, pg_temp`.

**VACUUM** cannot be executed inside a transaction block.

For tables with GIN indexes, **VACUUM** (in any form) also completes any pending index insertions, by moving pending index entries to the appropriate places in the main GIN index structure. See Section 65.4.4.1 for details.

We recommend that all databases be vacuumed regularly in order to remove dead rows. PostgreSQL includes an “autovacuum” facility which can automate routine vacuum maintenance. For more information about automatic and manual vacuuming, see Section 24.1.

The **FULL** option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. **VACUUM FULL** will usually shrink the table more than a plain **VACUUM** would.

The **PARALLEL** option is used only for vacuum purposes. If this option is specified with the **ANALYZE** option, it does not affect **ANALYZE**.

**VACUUM** causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based vacuum delay feature. For parallel vacuum, each worker sleeps in proportion to the work done by that worker. See Section 19.10.2 for details.

Each backend running **VACUUM** without the **FULL** option will report its progress in the `pg_stat_progress_vacuum` view. Backends running **VACUUM FULL** will instead report their progress in the `pg_stat_progress_cluster` view. See Section 27.4.5 and Section 27.4.2 for details.

## Examples

To clean a single table `onek`, analyze it for the optimizer and print a detailed vacuum activity report:

```
VACUUM (VERBOSE, ANALYZE) onek;
```

## Compatibility

There is no **VACUUM** statement in the SQL standard.

The following syntax was used before PostgreSQL version 9.0 and is still supported:

```
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] [ ANALYZE ]  
[ table_and_columns [, ...] ]
```

Note that in this syntax, the options must be specified in exactly the order shown.

# VALUES

VALUES — compute a set of rows

## Synopsis

```
VALUES ( expression [, ...] ) [, ...]
  [ ORDER BY sort_expression [ ASC | DESC | USING operator ]
  [, ...] ]
  [ LIMIT { count | ALL } ]
  [ OFFSET start [ ROW | ROWS ] ]
  [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
```

## Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a “constant table” within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table's columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION (see Section 10.5).

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDER BY, LIMIT (or equivalently FETCH FIRST), and OFFSET clauses with a VALUES command.

## Parameters

*expression*

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an *expression* can be replaced by DEFAULT to indicate that the destination column's default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

*sort\_expression*

An expression or integer constant indicating how to sort the result rows. This expression can refer to the columns of the VALUES result as `column1`, `column2`, etc. For more details see ORDER BY Clause in the SELECT documentation.

*operator*

A sorting operator. For details see ORDER BY Clause in the SELECT documentation.

*count*

The maximum number of rows to return. For details see LIMIT Clause in the SELECT documentation.

*start*

The number of rows to skip before starting to return rows. For details see LIMIT Clause in the SELECT documentation.

## Notes

VALUES lists with very large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

## Examples

A bare VALUES command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It's effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```
SELECT f.*
FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t
(studio, kind)
WHERE f.studio = t.studio AND f.kind = t.kind;
```

```
UPDATE employees SET salary = salary * v.increase
FROM (VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno,
target, increase)
WHERE employees.depno = v.depno AND employees.sales >= v.target;
```

Note that an AS clause is required when VALUES is used in a FROM clause, just as is true for SELECT. It is not required that the AS clause specify names for all the columns, but it's good practice to do so. (The default column names for VALUES are column1, column2, etc. in PostgreSQL, but these names might be different in other database systems.)

When VALUES is used in INSERT, the values are all automatically coerced to the data type of the corresponding destination column. When it's used in other contexts, it might be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines
WHERE ip_address IN (VALUES('192.168.0.1'::inet), ('192.168.0.10'),
('192.168.1.43'));
```

**Tip**

For simple **IN** tests, it's better to rely on the list-of-scalars form of **IN** than to write a **VALUES** query as shown above. The list of scalars method requires less writing and is often more efficient.

## Compatibility

**VALUES** conforms to the SQL standard. **LIMIT** and **OFFSET** are PostgreSQL extensions; see also under **SELECT**.

## See Also

**INSERT**, **SELECT**

---

# PostgreSQL Client Applications

This part contains reference information for PostgreSQL client applications and utilities. Not all of these commands are of general utility; some might require special privileges. The common feature of these applications is that they can be run on any host, independent of where the database server resides.

When specified on the command line, user and database names have their case preserved — the presence of spaces or special characters might require quoting. Table names and other identifiers do not have their case preserved, except where documented, and might require quoting.

# clusterdb

clusterdb — cluster a PostgreSQL database

## Synopsis

```
clusterdb [connection-option...] [option...] [ --table | -t table ] ... [ dbname | -a | --all ]
```

## Description

clusterdb is a utility for recluster tables in a PostgreSQL database. It finds tables that have previously been clustered, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

clusterdb is a wrapper around the SQL command CLUSTER. There is no effective difference between clustering databases via this utility and via other methods for accessing the server.

## Options

clusterdb accepts the following command-line arguments:

*-a*  
*--all*

Cluster all databases.

[ *-d* ] *dbname*  
[ *--dbname=* ] *dbname*

Specifies the name of the database to be clustered, when *-a*/*--all* is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

*-e*  
*--echo*

Echo the commands that clusterdb generates and sends to the server.

*-q*  
*--quiet*

Do not display progress messages.

*-t table*  
*--table=table*

Cluster *table* only. Multiple tables can be clustered by writing multiple *-t* switches.

*-v*  
*--verbose*

Print detailed information during processing.

*-V*  
*--version*

Print the clusterdb version and exit.

`-?`

`--help`

Show help about clusterdb command line arguments, and exit.

clusterdb also accepts the following command-line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force clusterdb to prompt for a password before connecting to a database.

This option is never essential, since clusterdb will automatically prompt for a password if the server demands password authentication. However, clusterdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--maintenance-db=dbname`

When the `-a/-all` is used, connect to this database to gather the list of databases to cluster. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

## Environment

`PGDATABASE`

`PGHOST`

`PGPORT`

`PGUSER`

Default connection parameters

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `CLUSTER` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To cluster the database `test`:

```
$ clusterdb test
```

To cluster a single table `foo` in a database named `xyzyz`:

```
$ clusterdb --table=foo xyzyz
```

## See Also

`CLUSTER`

---

# createdb

createdb — create a new PostgreSQL database

## Synopsis

```
createdb [connection-option...] [option...] [dbname] [description]
```

## Description

createdb creates a new PostgreSQL database.

Normally, the database user who executes this command becomes the owner of the new database. However, a different owner can be specified via the `-O` option, if the executing user has appropriate privileges.

createdb is a wrapper around the SQL command `CREATE DATABASE`. There is no effective difference between creating databases via this utility and via other methods for accessing the server.

## Options

createdb accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be created. The name must be unique among all PostgreSQL databases in this cluster. The default is to create a database with the same name as the current system user.

*description*

Specifies a comment to be associated with the newly created database.

`-D tablespace`

`--tablespace=tablespace`

Specifies the default tablespace for the database. (This name is processed as a double-quoted identifier.)

`-e`

`--echo`

Echo the commands that createdb generates and sends to the server.

`-E encoding`

`--encoding=encoding`

Specifies the character encoding scheme to be used in this database. The character sets supported by the PostgreSQL server are described in Section 23.3.1.

`-l locale`

`--locale=locale`

Specifies the locale to be used in this database. This is equivalent to specifying `--lc-collate`, `--lc-ctype`, and `--icu-locale` to the same value. Some locales are only valid for ICU and must be set with `--icu-locale`.

`--lc-collate=locale`

Specifies the LC\_COLLATE setting to be used in this database.

`--lc-ctype=locale`

Specifies the LC\_CTYPE setting to be used in this database.

`--builtin-locale=locale`

Specifies the locale name when the builtin provider is used. Locale support is described in Section 23.1.

`--icu-locale=locale`

Specifies the ICU locale ID to be used in this database, if the ICU locale provider is selected.

`--icu-rules=rules`

Specifies additional collation rules to customize the behavior of the default collation of this database. This is supported for ICU only.

`--locale-provider={builtin|libc|icu}`

Specifies the locale provider for the database's default collation.

`-O owner`

`--owner=owner`

Specifies the database user who will own the new database. (This name is processed as a double-quoted identifier.)

`-S strategy`

`--strategy=strategy`

Specifies the database creation strategy. See CREATE DATABASE STRATEGY for more details.

`-T template`

`--template=template`

Specifies the template database from which to build this database. (This name is processed as a double-quoted identifier.)

`-V`

`--version`

Print the createdb version and exit.

`-?`

`--help`

Show help about createdb command line arguments, and exit.

The options `-D`, `-l`, `-E`, `-O`, and `-T` correspond to options of the underlying SQL command `CREATE DATABASE`; see there for more information about them.

createdb also accepts the following command-line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

**-p *port***  
**--port=*port***

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

**-U *username***  
**--username=*username***

User name to connect as.

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**  
**--password**

Force createdb to prompt for a password before connecting to a database.

This option is never essential, since createdb will automatically prompt for a password if the server demands password authentication. However, createdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

**--maintenance-db=*dbname***

Specifies the name of the database to connect to when creating the new database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the new database being created), `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options.

## Environment

**PGDATABASE**

If set, the name of the database to create, unless overridden on the command line.

**PGHOST**  
**PGPORT**  
**PGUSER**

Default connection parameters. **PGUSER** also determines the name of the database to create, if it is not specified on the command line or by **PGDATABASE**.

**PG\_COLOR**

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `CREATE DATABASE` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To create the database `demo` using the default database server:

```
$ createdb demo
```

To create the database `demo` using the server on host `eden`, port `5000`, using the `template0` template database, here is the command-line command and the underlying SQL command:

```
$ createdb -p 5000 -h eden -T template0 -e demo
CREATE DATABASE demo TEMPLATE template0;
```

---

# createuser

createuser — define a new PostgreSQL user account

## Synopsis

```
createuser [connection-option...] [option...] [username]
```

## Description

createuser creates a new PostgreSQL user (or more precisely, a role). Only superusers and users with CREATEROLE privilege can create new users, so createuser must be invoked by someone who can connect as a superuser or a user with CREATEROLE privilege.

If you wish to create a role with the SUPERUSER, REPLICATION, or BYPASSRLS privilege, you must connect as a superuser, not merely with CREATEROLE privilege. Being a superuser implies the ability to bypass all access permission checks within the database, so superuser access should not be granted lightly. CREATEROLE also conveys very extensive privileges.

createuser is a wrapper around the SQL command CREATE ROLE. There is no effective difference between creating users via this utility and via other methods for accessing the server.

## Options

createuser accepts the following command-line arguments:

*username*

Specifies the name of the PostgreSQL user to be created. This name must be different from all existing roles in this PostgreSQL installation.

**-a** *role*

**--with-admin=***role*

Specifies an existing role that will be automatically added as a member of the new role with admin option, giving it the right to grant membership in the new role to others. Multiple existing roles can be specified by writing multiple **-a** switches.

**-c** *number*

**--connection-limit=***number*

Set a maximum number of connections for the new user. The default is to set no limit.

**-d**

**--createdb**

The new user will be allowed to create databases.

**-D**

**--no-createdb**

The new user will not be allowed to create databases. This is the default.

**-e**

**--echo**

Echo the commands that createuser generates and sends to the server.

-E  
--encrypted

This option is obsolete but still accepted for backward compatibility.

-g *role*  
--member-of=*role*  
--role=*role* (deprecated)

Specifies the new role should be automatically added as a member of the specified existing role. Multiple existing roles can be specified by writing multiple -g switches.

-i  
--inherit

The new role will automatically inherit privileges of roles it is a member of. This is the default.

-I  
--no-inherit

The new role will not automatically inherit privileges of roles it is a member of.

--interactive

Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options -d/-D, -r/-R, -s/-S is not specified on the command line. (This was the default behavior up to PostgreSQL 9.1.)

-l  
--login

The new user will be allowed to log in (that is, the user name can be used as the initial session user identifier). This is the default.

-L  
--no-login

The new user will not be allowed to log in. (A role without login privilege is still useful as a means of managing database permissions.)

-m *role*  
--with-member=*role*

Specifies an existing role that will be automatically added as a member of the new role. Multiple existing roles can be specified by writing multiple -m switches.

-P  
--pwprompt

If given, createuser will issue a prompt for the password of the new user. This is not necessary if you do not plan on using password authentication.

-r  
--createrole

The new user will be allowed to create, alter, drop, comment on, change the security label for other roles; that is, this user will have CREATEROLE privilege. See role creation for more details about what capabilities are conferred by this privilege.

-R  
--no-createrole

The new user will not be allowed to create new roles. This is the default.

-s  
--superuser

The new user will be a superuser.

-S  
--no-superuser

The new user will not be a superuser. This is the default.

-v *timestamp*  
--valid-until=*timestamp*

Set a date and time after which the role's password is no longer valid. The default is to set no password expiry date.

-V  
--version

Print the createuser version and exit.

--bypassrls

The new user will bypass every row-level security (RLS) policy.

--no-bypassrls

The new user will not bypass row-level security (RLS) policies. This is the default.

--replication

The new user will have the **REPLICATION** privilege, which is described more fully in the documentation for **CREATE ROLE**.

--no-replication

The new user will not have the **REPLICATION** privilege, which is described more fully in the documentation for **CREATE ROLE**. This is the default.

-?  
--help

Show help about createuser command line arguments, and exit.

createuser also accepts the following command-line arguments for connection parameters:

-h *host*  
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U *username*  
--username=*username*

User name to connect as (not the user name to create).

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**  
**--password**

Force createuser to prompt for a password (for connecting to the server, not for the password of the new user).

This option is never essential, since createuser will automatically prompt for a password if the server demands password authentication. However, createuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing **-W** to avoid the extra connection attempt.

## Environment

**PGHOST**  
**PGPORT**  
**PGUSER**

Default connection parameters

**PG\_COLOR**

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `CREATE ROLE` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To create a user `joe` on the default database server:

```
$ createuser joe
```

To create a user `joe` on the default database server with prompting for some additional attributes:

```
$ createuser --interactive joe
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n
```

To create the same user `joe` using the server on host `eden`, port 5000, with attributes explicitly specified, taking a look at the underlying command:

```
$ createuser -h eden -p 5000 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;
```

To create the user `joe` as a superuser, and assign a password immediately:

```
$ createuser -P -s -e joe
Enter password for new role: xyzzzy
Enter it again: xyzzzy
CREATE ROLE joe PASSWORD 'SCRAM-SHA-256$4096:44560wPMLfjqIAzyPDZ/
eQ==$4CA054rZlSFEq8Z3FEhToBTa2X6KnWFxFkPwIbKoDe0=:L/
nbSZRCjp6Rh0hKK56GoR1zibCCSePKshCJ9lnl3yw=' SUPERUSER CREATEDB
CREATEROLE INHERIT LOGIN NOREPLICATION NOBYPASSRLS;
```

In the above example, the new password isn't actually echoed when typed, but we show what was typed for clarity. As you see, the password is encrypted before it is sent to the client.

# dropdb

dropdb — remove a PostgreSQL database

## Synopsis

dropdb [*connection-option...*] [*option...*] *dbname*

## Description

dropdb destroys an existing PostgreSQL database. The user who executes this command must be a database superuser or the owner of the database.

dropdb is a wrapper around the SQL command `DROP DATABASE`. There is no effective difference between dropping databases via this utility and via other methods for accessing the server.

## Options

dropdb accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be removed.

`-e`  
`--echo`

Echo the commands that dropdb generates and sends to the server.

`-f`  
`--force`

Attempt to terminate all existing connections to the target database before dropping it. See `DROP DATABASE` for more information on this option.

`-i`  
`--interactive`

Issues a verification prompt before doing anything destructive.

`-V`  
`--version`

Print the dropdb version and exit.

`--if-exists`

Do not throw an error if the database does not exist. A notice is issued in this case.

`-?`  
`--help`

Show help about dropdb command line arguments, and exit.

dropdb also accepts the following command-line arguments for connection parameters:

**-h** *host*  
**--host=***host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

**-p** *port*  
**--port=***port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

**-U** *username*  
**--username=***username*

User name to connect as.

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**  
**--password**

Force dropdb to prompt for a password before connecting to a database.

This option is never essential, since dropdb will automatically prompt for a password if the server demands password authentication. However, dropdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

**--maintenance-db=***dbname*

Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or is the database being dropped), `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options.

## Environment

PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `DROP DATABASE` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To destroy the database `demo` on the default database server:

```
$ dropdb demo
```

To destroy the database `demo` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropdb -p 5000 -h eden -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE demo;
```

# dropuser

dropuser — remove a PostgreSQL user account

## Synopsis

dropuser [*connection-option...*] [*option...*] [*username*]

## Description

dropuser removes an existing PostgreSQL user. Superusers can use this command to remove any role; otherwise, only non-superuser roles can be removed, and only by a user who possesses the `CREATE-ROLE` privilege and has been granted `ADMIN OPTION` on the target role.

dropuser is a wrapper around the SQL command `DROP ROLE`. There is no effective difference between dropping users via this utility and via other methods for accessing the server.

## Options

dropuser accepts the following command-line arguments:

*username*

Specifies the name of the PostgreSQL user to be removed. You will be prompted for a name if none is specified on the command line and the `-i/--interactive` option is used.

`-e`  
`--echo`

Echo the commands that dropuser generates and sends to the server.

`-i`  
`--interactive`

Prompt for confirmation before actually removing the user, and prompt for the user name if none is specified on the command line.

`-V`  
`--version`

Print the dropuser version and exit.

`--if-exists`

Do not throw an error if the user does not exist. A notice is issued in this case.

`-?`  
`--help`

Show help about dropuser command line arguments, and exit.

dropuser also accepts the following command-line arguments for connection parameters:

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

**-p** *port*  
**--port=***port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

**-U** *username*  
**--username=***username*

User name to connect as (not the user name to drop).

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**  
**--password**

Force dropuser to prompt for a password before connecting to a database.

This option is never essential, since dropuser will automatically prompt for a password if the server demands password authentication. However, dropuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing **-W** to avoid the extra connection attempt.

## Environment

PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `DROP ROLE` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To remove user `joe` from the default database server:

**\$ dropuser joe**

To remove user `joe` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropuser -p 5000 -h eden -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE joe;
```

---

# ecpg

ecpg — embedded SQL C preprocessor

## Synopsis

ecpg [*option...*] *file...*

## Description

ecpg is the embedded SQL preprocessor for C programs. It converts C programs with embedded SQL statements to normal C code by replacing the SQL invocations with special function calls. The output files can then be processed with any C compiler tool chain.

ecpg will convert each input file given on the command line to the corresponding C output file. If an input file name does not have any extension, `.pgc` is assumed. The file's extension will be replaced by `.c` to construct the output file name. But the output file name can be overridden using the `-o` option.

If an input file name is just `-`, `ecpg` reads the program from standard input (and writes to standard output, unless that is overridden with `-o`).

This reference page does not describe the embedded SQL language. See Chapter 34 for more information on that topic.

## Options

ecpg accepts the following command-line arguments:

`-c`

Automatically generate certain C code from SQL code. Currently, this works for EXEC SQL TYPE.

`-C mode`

Set a compatibility mode. *mode* can be INFORMIX, INFORMIX\_SE, or ORACLE.

`-D symbol[=value]`

Define a preprocessor symbol, equivalently to the EXEC SQL DEFINE directive. If no *value* is specified, the symbol is defined with the value 1.

`-h`

Process header files. When this option is specified, the output file extension becomes `.h` not `.c`, and the default input file extension is `.pgh` not `.pgc`. Also, the `-c` option is forced on.

`-i`

Parse system include files as well.

`-I directory`

Specify an additional include path, used to find files included via EXEC SQL INCLUDE. Defaults are `.` (current directory), `/usr/local/include`, the PostgreSQL include directory which is defined at compile time (default: `/usr/local/pgsql/include`), and `/usr/include`, in that order.

**-o *filename***

Specifies that `ecpg` should write all its output to the given *filename*. Write `-o -` to send all output to standard output.

**-r *option***

Selects run-time behavior. *Option* can be one of the following:

**no\_indicator**

Do not use indicators but instead use special values to represent null values. Historically there have been databases using this approach.

**prepare**

Prepare all statements before using them. Libecpg will keep a cache of prepared statements and reuse a statement if it gets executed again. If the cache runs full, libecpg will free the least used statement.

**questionmarks**

Allow question mark as placeholder for compatibility reasons. This used to be the default long ago.

**-t**

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when `EXEC SQL COMMIT` is issued.

**-v**

Print additional information including the version and the "include" path.

**--version**

Print the `ecpg` version and exit.

**-?****--help**

Show help about `ecpg` command line arguments, and exit.

## Notes

When compiling the preprocessed C code files, the compiler needs to be able to find the ECPG header files in the PostgreSQL include directory. Therefore, you might have to use the `-I` option when invoking the compiler (e.g., `-I/usr/local/pgsql/include`).

Programs using C code with embedded SQL have to be linked against the `libecpg` library, for example using the linker options `-L/usr/local/pgsql/lib -lecpg`.

The value of either of these directories that is appropriate for the installation can be found out using `pg_config`.

## Examples

If you have an embedded SQL C source file named `prog1.pgc`, you can create an executable program using the following sequence of commands:

```
ecpg prog1.pgc  
cc -I/usr/local/pgsql/include -c prog1.c  
cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpq
```

---

# pg\_amcheck

pg\_amcheck — checks for corruption in one or more PostgreSQL databases

## Synopsis

```
pg_amcheck [option...] [dbname]
```

## Description

pg\_amcheck supports running amcheck's corruption checking functions against one or more databases, with options to select which schemas, tables and indexes to check, which kinds of checking to perform, and whether to perform the checks in parallel, and if so, the number of parallel connections to establish and use.

Only ordinary and toast table relations, materialized views, sequences, and btree indexes are currently supported. Other relation types are silently skipped.

If *dbname* is specified, it should be the name of a single database to check, and no other database selection options should be present. Otherwise, if any database selection options are present, all matching databases will be checked. If no such options are present, the default database will be checked. Database selection options include `--all`, `--database` and `--exclude-database`. They also include `--relation`, `--exclude-relation`, `--table`, `--exclude-table`, `--index`, and `--exclude-index`, but only when such options are used with a three-part pattern (e.g. `mydb*.myschema*.myrel*`). Finally, they include `--schema` and `--exclude-schema` when such options are used with a two-part pattern (e.g. `mydb*.myschema*`).

*dbname* can also be a connection string.

## Options

The following command-line options control what is checked:

`-a`  
`--all`

Check all databases, except for any excluded via `--exclude-database`.

`-d pattern`  
`--database=pattern`

Check databases matching the specified *pattern*, except for any excluded by `--exclude-database`. This option can be specified more than once.

`-D pattern`  
`--exclude-database=pattern`

Exclude databases matching the given *pattern*. This option can be specified more than once.

`-i pattern`  
`--index=pattern`

Check indexes matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

This is similar to the `--relation` option, except that it applies only to indexes, not to other relation types.

**-I *pattern***  
**--exclude-index=*pattern***

Exclude indexes matching the specified *pattern*. This option can be specified more than once.

This is similar to the **--exclude-relation** option, except that it applies only to indexes, not other relation types.

**-r *pattern***  
**--relation=*pattern***

Check relations matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

Patterns may be unqualified, e.g. *myrel\**, or they may be schema-qualified, e.g. *myschema\*.myrel\** or database-qualified and schema-qualified, e.g. *mydb\*.myschema\*.myrel\**. A database-qualified pattern will add matching databases to the list of databases to be checked.

**-R *pattern***  
**--exclude-relation=*pattern***

Exclude relations matching the specified *pattern*. This option can be specified more than once.

As with **--relation**, the *pattern* may be unqualified, schema-qualified, or database- and schema-qualified.

**-s *pattern***  
**--schema=*pattern***

Check tables and indexes in schemas matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

To select only tables in schemas matching a particular pattern, consider using something like **--table=SCHEMAPAT.\* --no-dependent-indexes**. To select only indexes, consider using something like **--index=SCHEMAPAT.\***.

A schema pattern may be database-qualified. For example, you may write **--schema=mydb\*.myschema\*** to select schemas matching *myschema\** in databases matching *mydb\**.

**-S *pattern***  
**--exclude-schema=*pattern***

Exclude tables and indexes in schemas matching the specified *pattern*. This option can be specified more than once.

As with **--schema**, the pattern may be database-qualified.

**-t *pattern***  
**--table=*pattern***

Check tables matching the specified *pattern*, unless they are otherwise excluded. This option can be specified more than once.

This is similar to the **--relation** option, except that it applies only to tables, materialized views, and sequences, not to indexes.

**-T *pattern***  
**--exclude-table=*pattern***

Exclude tables matching the specified *pattern*. This option can be specified more than once.

This is similar to the `--exclude-relation` option, except that it applies only to tables, materialized views, and sequences, not to indexes.

#### `--no-dependent-indexes`

By default, if a table is checked, any btree indexes of that table will also be checked, even if they are not explicitly selected by an option such as `--index` or `--relation`. This option suppresses that behavior.

#### `--no-dependent-toast`

By default, if a table is checked, its toast table, if any, will also be checked, even if it is not explicitly selected by an option such as `--table` or `--relation`. This option suppresses that behavior.

#### `--no-strict-names`

By default, if an argument to `--database`, `--table`, `--index`, or `--relation` matches no objects, it is a fatal error. This option downgrades that error to a warning.

The following command-line options control checking of tables:

#### `--exclude-toast-pointers`

By default, whenever a toast pointer is encountered in a table, a lookup is performed to ensure that it references apparently-valid entries in the toast table. These checks can be quite slow, and this option can be used to skip them.

#### `--on-error-stop`

After reporting all corruptions on the first page of a table where corruption is found, stop processing that table relation and move on to the next table or index.

Note that index checking always stops after the first corrupt page. This option only has meaning relative to table relations.

#### `--skip=option`

If `all-frozen` is given, table corruption checks will skip over pages in all tables that are marked as all frozen.

If `all-visible` is given, table corruption checks will skip over pages in all tables that are marked as all visible.

By default, no pages are skipped. This can be specified as `none`, but since this is the default, it need not be mentioned.

#### `--startblock=block`

Start checking at the specified block number. An error will occur if the table relation being checked has fewer than this number of blocks. This option does not apply to indexes, and is probably only useful when checking a single table relation. See `--endblock` for further caveats.

#### `--endblock=block`

End checking at the specified block number. An error will occur if the table relation being checked has fewer than this number of blocks. This option does not apply to indexes, and is probably only useful when checking a single table relation. If both a regular table and a toast table are checked, this option will apply to both, but higher-numbered toast blocks may still be accessed while validating toast pointers, unless that is suppressed using `--exclude-toast-pointers`.

The following command-line options control checking of B-tree indexes:

**--checkunique**

For each index with unique constraint checked, verify that no more than one among duplicate entries is visible in the index using amcheck's `checkunique` option.

**--heapallindexed**

For each index checked, verify the presence of all heap tuples as index tuples in the index using amcheck's `heapallindexed` option.

**--parent-check**

For each btree index checked, use amcheck's `bt_index_parent_check` function, which performs additional checks of parent/child relationships during index checking.

The default is to use amcheck's `bt_index_check` function, but note that use of the `--root-descend` option implicitly selects `bt_index_parent_check`.

**--rootdescend**

For each index checked, re-find tuples on the leaf level by performing a new search from the root page for each tuple using amcheck's `rootdescend` option.

Use of this option implicitly also selects the `--parent-check` option.

This form of verification was originally written to help in the development of btree index features. It may be of limited use or even of no use in helping detect the kinds of corruption that occur in practice. It may also cause corruption checking to take considerably longer and consume considerably more resources on the server.

### Warning

The extra checks performed against B-tree indexes when the `--parent-check` option or the `--rootdescend` option is specified require relatively strong relation-level locks. These checks are the only checks that will block concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands.

The following command-line options control the connection to the server:

**-h *hostname***

**--host=*hostname***

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

**-p *port***

**--port=*port***

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

**-U**

**--username=*username***

User name to connect as.

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**  
**--password**

Force `pg_amcheck` to prompt for a password before connecting to a database.

This option is never essential, since `pg_amcheck` will automatically prompt for a password if the server demands password authentication. However, `pg_amcheck` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

**--maintenance-db=*dbname***

Specifies a database or connection string to be used to discover the list of databases to be checked. If neither `--all` nor any option including a database pattern is used, no such connection is required and this option does nothing. Otherwise, any connection string parameters other than the database name which are included in the value for this option will also be used when connecting to the databases being checked. If this option is omitted, the default is `postgres` or, if that fails, `template1`.

Other options are also available:

**-e**  
**--echo**

Echo to stdout all SQL sent to the server.

**-j *num***  
**--jobs=*num***

Use *num* concurrent connections to the server, or one per object to be checked, whichever is less.

The default is to use a single connection.

**-P**  
**--progress**

Show progress information. Progress information includes the number of relations for which checking has been completed, and the total size of those relations. It also includes the total number of relations that will eventually be checked, and the estimated size of those relations.

**-v**  
**--verbose**

Print more messages. In particular, this will print a message for each relation being checked, and will increase the level of detail shown for server errors.

**-V**  
**--version**

Print the `pg_amcheck` version and exit.

**--install-missing**  
**--install-missing=*schema***

Install any missing extensions that are required to check the database(s). If not yet installed, each extension's objects will be installed into the given *schema*, or if not specified into schema `pg_catalog`.

At present, the only required extension is amcheck.

-?  
--help

Show help about pg\_amcheck command line arguments, and exit.

## Environment

pg\_amcheck, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

pg\_amcheck is designed to work with PostgreSQL 14.0 and later.

# pg\_basebackup

pg\_basebackup — take a base backup of a PostgreSQL cluster

## Synopsis

pg\_basebackup [*option...*]

## Description

pg\_basebackup is used to take a base backup of a running PostgreSQL database cluster. The backup is taken without affecting other clients of the database, and can be used both for point-in-time recovery (see Section 25.3) and as the starting point for a log-shipping or streaming-replication standby server (see Section 26.2).

pg\_basebackup can take a full or incremental base backup of the database. When used to take a full backup, it makes an exact copy of the database cluster's files. When used to take an incremental backup, some files that would have been part of a full backup may be replaced with incremental versions of the same files, containing only those blocks that have been modified since the reference backup. An incremental backup cannot be used directly; instead, pg\_combinebackup must first be used to combine it with the previous backups upon which it depends. See Section 25.3.3 for more information about incremental backups, and Section 25.3.5 for steps to recover from a backup.

In any mode, pg\_basebackup makes sure the server is put into and out of backup mode automatically. Backups are always taken of the entire database cluster; it is not possible to back up individual databases or database objects. For selective backups, another tool such as pg\_dump must be used.

The backup is made over a regular PostgreSQL connection that uses the replication protocol. The connection must be made with a user ID that has `REPLICATION` permissions (see Section 21.2) or is a superuser, and `pg_hba.conf` must permit the replication connection. The server must also be configured with `max_wal_senders` set high enough to provide at least one walsender for the backup plus one for WAL streaming (if used).

There can be multiple pg\_basebackups running at the same time, but it is usually better from a performance point of view to take only one backup, and copy the result.

pg\_basebackup can make a base backup from not only a primary server but also a standby. To take a backup from a standby, set up the standby so that it can accept replication connections (that is, set `max_wal_senders` and `hot_standby`, and configure its `pg_hba.conf` appropriately). You will also need to enable `full_page_writes` on the primary.

Note that there are some limitations in taking a backup from a standby:

- The backup history file is not created in the database cluster backed up.
- pg\_basebackup cannot force the standby to switch to a new WAL file at the end of backup. When you are using `-X none`, if write activity on the primary is low, pg\_basebackup may need to wait a long time for the last WAL file required for the backup to be switched and archived. In this case, it may be useful to run `pg_switch_wal` on the primary in order to trigger an immediate WAL file switch.
- If the standby is promoted to be primary during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes, which requires you to enable `full_page_writes` on the primary.

Whenever pg\_basebackup is taking a base backup, the server's `pg_stat_progress_basebackup` view will report the progress of the backup. See Section 27.4.6 for details.

## Options

The following command-line options control the location and format of the output:

`-D directory`  
`--pgdata=directory`

Sets the target directory to write the output to. `pg_basebackup` will create this directory (and any missing parent directories) if it does not exist. If it already exists, it must be empty.

When the backup is in tar format, the target directory may be specified as `-` (dash), causing the tar file to be written to `stdout`.

This option is required.

`-F format`  
`--format=format`

Selects the format for the output. *format* can be one of the following:

`p`  
`plain`

Write the output as plain files, with the same layout as the source server's data directory and tablespaces. When the cluster has no additional tablespaces, the whole database will be placed in the target directory. If the cluster contains additional tablespaces, the main data directory will be placed in the target directory, but all other tablespaces will be placed in the same absolute path as they have on the source server. (See `--tablespace-mapping` to change that.)

This is the default format.

`t`  
`tar`

Write the output as tar files in the target directory. The main data directory's contents will be written to a file named `base.tar`, and each other tablespace will be written to a separate tar file named after that tablespace's OID.

If the target directory is specified as `-` (dash), the tar contents will be written to standard output, suitable for piping to (for example) `gzip`. This is only allowed if the cluster has no additional tablespaces and WAL streaming is not used.

`-i old_manifest_file`  
`--incremental=old_manifest_file`

Performs an incremental backup. The backup manifest for the reference backup must be provided, and will be uploaded to the server, which will respond by sending the requested incremental backup.

`-R`  
`--write-recovery-conf`

Creates a `standby.signal` file and appends connection settings to the `postgresql.auto.conf` file in the target directory (or within the base archive file when using tar format). This eases setting up a standby server using the results of the backup.

The `postgresql.auto.conf` file will record the connection settings and, if specified, the replication slot that `pg_basebackup` is using, so that streaming replication and logical replication slot synchronization will use the same settings later on. The `dbname` will be recorded only if the `dbname` was specified explicitly in the connection string or environment variable.

**-t** *target*  
**--target=***target*

Instructs the server where to place the base backup. The default target is `client`, which specifies that the backup should be sent to the machine where `pg_basebackup` is running. If the target is instead set to `server:/some/path`, the backup will be stored on the machine where the server is running in the `/some/path` directory. Storing a backup on the server requires superuser privileges or having privileges of the `pg_write_server_files` role. If the target is set to `blackhole`, the contents are discarded and not stored anywhere. This should only be used for testing purposes, as you will not end up with an actual backup.

Since WAL streaming is implemented by `pg_basebackup` rather than by the server, this option cannot be used together with `-Xstream`. Since that is the default, when this option is specified, you must also specify either `-Xfetch` or `-Xnone`.

**-T** *olddir=newdir*  
**--tablespace-mapping=***olddir=newdir*

Relocates the tablespace in directory *olddir* to *newdir* during the backup. To be effective, *olddir* must exactly match the path specification of the tablespace as it is defined on the source server. (But it is not an error if there is no tablespace in *olddir* on the source server.) Meanwhile *newdir* is a directory in the receiving host's filesystem. As with the main target directory, *newdir* need not exist already, but if it does exist it must be empty. Both *olddir* and *newdir* must be absolute paths. If either path needs to contain an equal sign (=), precede that with a backslash. This option can be specified multiple times for multiple tablespaces.

If a tablespace is relocated in this way, the symbolic links inside the main data directory are updated to point to the new location. So the new data directory is ready to be used for a new server instance with all tablespaces in the updated locations.

Currently, this option only works with plain output format; it is ignored if tar format is selected.

**--waldir=***waldir*

Sets the directory to write WAL (write-ahead log) files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. *waldir* must be an absolute path. As with the main target directory, *waldir* need not exist already, but if it does exist it must be empty. This option can only be specified when the backup is in plain format.

**-X** *method*  
**--wal-method=***method*

Includes the required WAL (write-ahead log) files in the backup. This will include all write-ahead logs generated during the backup. Unless the method `none` is specified, it is possible to start a postmaster in the target directory without the need to consult the WAL archive, thus making the output a completely standalone backup.

The following *methods* for collecting the write-ahead logs are supported:

**n**  
**none**

Don't include write-ahead logs in the backup.

**f**  
**fetch**

The write-ahead log files are collected at the end of the backup. Therefore, it is necessary for the source server's `wal_keep_size` parameter to be set high enough that the required log data

is not removed before the end of the backup. If the required log data has been recycled before it's time to transfer it, the backup will fail and be unusable.

When tar format is used, the write-ahead log files will be included in the `base.tar` file.

## S stream

Stream write-ahead log data while the backup is being taken. This method will open a second connection to the server and start streaming the write-ahead log in parallel while running the backup. Therefore, it will require two replication connections not just one. As long as the client can keep up with the write-ahead log data, using this method requires no extra write-ahead logs to be saved on the source server.

When tar format is used, the write-ahead log files will be written to a separate file named `pg_wal.tar` (if the server is a version earlier than 10, the file will be named `pg_xlog.tar`).

This value is the default.

## -Z --gzip

Enables gzip compression of tar file output, with the default compression level. Compression is only available when using the tar format, and the suffix `.gz` will automatically be added to all tar filenames.

## -Z *level* -Z [{*client*|*server*}-]*method*[:*detail*] --compress=*level* --compress=[{*client*|*server*}-]*method*[:*detail*]

Requests compression of the backup. If *client* or *server* is included, it specifies where the compression is to be performed. Compressing on the server will reduce transfer bandwidth but will increase server CPU consumption. The default is *client* except when `--target` is used. In that case, the backup is not being sent to the client, so only server compression is sensible. When `-Xstream`, which is the default, is used, server-side compression will not be applied to the WAL. To compress the WAL, use client-side compression, or specify `-Xfetch`.

The compression method can be set to `gzip`, `lz4`, `zstd`, `none` for no compression or an integer (no compression if 0, `gzip` if greater than 0). A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form *keyword* or *keyword=value*. Currently, the supported keywords are `level`, `long`, and `workers`. The detail string cannot be used when the compression method is specified as a plain integer.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, `gzip` compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

When the tar format is used with `gzip`, `lz4`, or `zstd`, the suffix `.gz`, `.lz4`, or `.zst`, respectively, will be automatically added to all tar filenames. When the plain format is used, client-side compression may not be specified, but it is still possible to request server-side compression. If this is done, the server will compress the backup for transmission, and the client will decompress and extract it.

When this option is used in combination with `-Xstream`, `pg_wal.tar` will be compressed using `gzip` if client-side gzip compression is selected, but will not be compressed if any other compression algorithm is selected, or if server-side compression is selected.

The following command-line options control the generation of the backup and the invocation of the program:

**-c {fast|spread}**  
**--checkpoint={fast|spread}**

Sets checkpoint mode to fast (immediate) or spread (the default) (see Section 25.3.4).

**-C**  
**--create-slot**

Specifies that the replication slot named by the **--slot** option should be created before starting the backup. An error is raised if the slot already exists.

**-l label**  
**--label=label**

Sets the label for the backup. If none is specified, a default value of “pg\_basebackup base backup” will be used.

**-n**  
**--no-clean**

By default, when **pg\_basebackup** aborts with an error, it removes any directories it might have created before discovering that it cannot finish the job (for example, the target directory and write-ahead log directory). This option inhibits tidying-up and is thus useful for debugging.

Note that tablespace directories are not cleaned up either way.

**-N**  
**--no-sync**

By default, **pg\_basebackup** will wait for all files to be written safely to disk. This option causes **pg\_basebackup** to return without waiting, which is faster, but means that a subsequent operating system crash can leave the base backup corrupt. Generally, this option is useful for testing but should not be used when creating a production installation.

**-P**  
**--progress**

Enables progress reporting. Turning this on will deliver an approximate progress report during the backup. Since the database may change during the backup, this is only an approximation and may not end at exactly 100%. In particular, when WAL log is included in the backup, the total amount of data cannot be estimated in advance, and in this case the estimated target size will increase once it passes the total estimate without WAL.

**-r rate**  
**--max-rate=rate**

Sets the maximum transfer rate at which data is collected from the source server. This can be useful to limit the impact of **pg\_basebackup** on the server. Values are in kilobytes per second. Use a suffix of M to indicate megabytes per second. A suffix of k is also accepted, and has no effect. Valid values are between 32 kilobytes per second and 1024 megabytes per second.

This option always affects transfer of the data directory. Transfer of WAL files is only affected if the collection method is **fetch**.

**-S slotname**  
**--slot=slotname**

This option can only be used together with **-X stream**. It causes WAL streaming to use the specified replication slot. If the base backup is intended to be used as a streaming-replication

standby using a replication slot, the standby should then use the same replication slot name as `primary_slot_name`. This ensures that the primary server does not remove any necessary WAL data in the time between the end of the base backup and the start of streaming replication on the new standby.

The specified replication slot has to exist unless the option `-C` is also used.

If this option is not specified and the server supports temporary replication slots (version 10 and later), then a temporary replication slot is automatically used for WAL streaming.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_basebackup` will recursively open and synchronize all files in the backup directory. When the plain format is used, the search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file system that contains the backup directory. When the plain format is used, `pg_basebackup` will also synchronize the file systems that contain the WAL files and each tablespace. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-v`

`--verbose`

Enables verbose mode. Will output some extra steps during startup and shutdown, as well as show the exact file name that is currently being processed if progress reporting is also enabled.

`--manifest-checksums=algorithm`

Specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are `NONE`, `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`. The default is `CRC32C`.

If `NONE` is selected, the backup manifest will not contain any checksums. Otherwise, it will contain a checksum of each file in the backup using the specified algorithm. In addition, the manifest will always contain a `SHA256` checksum of its own contents. The `SHA` algorithms are significantly more CPU-intensive than `CRC32C`, so selecting one of them may increase the time required to complete the backup.

Using a `SHA` hash function provides a cryptographically secure digest of each file for users who wish to verify that the backup has not been tampered with, while the `CRC-32C` algorithm provides a checksum that is much faster to calculate; it is good at catching errors due to accidental changes but is not resistant to malicious modifications. Note that, to be useful against an adversary who has access to the backup, the backup manifest would need to be stored securely elsewhere or otherwise verified not to have been modified since the backup was taken.

`pg_verifybackup` can be used to check the integrity of a backup against the backup manifest.

`--manifest-force-encode`

Forces all filenames in the backup manifest to be hex-encoded. If this option is not specified, only non-UTF8 filenames are hex-encoded. This option is mostly intended to test that tools which read a backup manifest file properly handle this case.

`--no-estimate-size`

Prevents the server from estimating the total amount of backup data that will be streamed, resulting in the `backup_total` column in the `pg_stat_progress_basebackup` view always being `NULL`.

Without this option, the backup will start by enumerating the size of the entire database, and then go back and send the actual contents. This may make the backup take slightly longer, and in particular it will take longer before the first data is sent. This option is useful to avoid such estimation time if it's too long.

This option is not allowed when using `--progress`.

#### `--no-manifest`

Disables generation of a backup manifest. If this option is not specified, the server will generate and send a backup manifest which can be verified using `pg_verifybackup`. The manifest is a list of every file present in the backup with the exception of any WAL files that may be included. It also stores the size, last modification time, and an optional checksum for each file.

#### `--no-slot`

Prevents the creation of a temporary replication slot for the backup.

By default, if log streaming is selected but no slot name is given with the `-S` option, then a temporary replication slot is created (if supported by the source server).

The main purpose of this option is to allow taking a base backup when the server has no free replication slots. Using a replication slot is almost always preferred, because it prevents needed WAL from being removed by the server during the backup.

#### `--no-verify-checksums`

Disables verification of checksums, if they are enabled on the server the base backup is taken from.

By default, checksums are verified and checksum failures will result in a non-zero exit status. However, the base backup will not be removed in such a case, as if the `--no-clean` option had been used. Checksum verification failures will also be reported in the `pg_stat_database` view.

The following command-line options control the connection to the source server:

#### `-d connstr`

##### `--dbname=connstr`

Specifies parameters used to connect to the server, as a connection string; these will override any conflicting command line options.

This option is called `--dbname` for consistency with other client applications, but because `pg_basebackup` doesn't connect to any particular database in the cluster, any database name included in the connection string will be ignored by the server. However, a database name supplied that way overrides the default database name (`replication`) for purposes of looking up the replication connection's password in `~/.pgpass`. Similarly, middleware or proxies used in connecting to PostgreSQL might utilize the name for purposes such as connection routing. The database name can also be used by logical replication slot synchronization.

#### `-h host`

##### `--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for a Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

#### `-p port`

##### `--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-s interval`  
`--status-interval=interval`

Specifies the number of seconds between status packets sent back to the source server. Smaller values allow more accurate monitoring of backup progress from the server. A value of zero disables periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout-based disconnects. The default value is 10 seconds.

`-U username`  
`--username=username`

Specifies the user name to connect as.

`-w`  
`--no-password`

Prevents issuing a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Forces `pg_basebackup` to prompt for a password before connecting to the source server.

This option is never essential, since `pg_basebackup` will automatically prompt for a password if the server demands password authentication. However, `pg_basebackup` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Other options are also available:

`-V`  
`--version`

Prints the `pg_basebackup` version and exits.

`-?`  
`--help`

Shows help about `pg_basebackup` command line arguments, and exits.

## Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by `libpq` (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

At the beginning of the backup, a checkpoint needs to be performed on the source server. This can take some time (especially if the option `--checkpoint=fast` is not used), during which `pg_basebackup` will appear to be idle.

The backup will include all files in the data directory and tablespaces, including the configuration files and any additional files placed in the directory by third parties, except certain temporary files managed by PostgreSQL and operating system files. But only regular files and directories are copied, except that symbolic links used for tablespaces are preserved. Symbolic links pointing to certain directories

known to PostgreSQL are copied as empty directories. Other symbolic links and special device files are skipped. See Section 54.4 for the precise details.

In plain format, tablespaces will be backed up to the same path they have on the source server, unless the option `--tablespace-mapping` is used. Without this option, running a plain format base backup on the same host as the server will not work if tablespaces are in use, because the backup would have to be written to the same directory locations as the original tablespaces.

When tar format is used, it is the user's responsibility to unpack each tar file before starting a PostgreSQL server that uses the data. If there are additional tablespaces, the tar files for them need to be unpacked in the correct locations. In this case the symbolic links for those tablespaces will be created by the server according to the contents of the `tablespace_map` file that is included in the `base.tar` file.

`pg_basebackup` works with servers of the same or older major version, down to 9.1. However, WAL streaming mode (`-X stream`) only works with server version 9.3 and later, the tar format (`--format=tar`) only works with server version 9.5 and later, and incremental backup (`--incremental`) only works with server version 17 and later.

`pg_basebackup` will preserve group permissions for data files if group permissions are enabled on the source cluster.

## Examples

To create a base backup of the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/data`:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
```

To create a backup of the local server with one compressed tar file for each tablespace, and store it in the directory `backup`, showing a progress report while running:

```
$ pg_basebackup -D backup -Ft -z -P
```

To create a backup of a single-tablespace local database and compress this with `bzip2`:

```
$ pg_basebackup -D - -Ft -X fetch | bzip2 > backup.tar.bz2
```

(This command will fail if there are multiple tablespaces in the database.)

To create a backup of a local database where the tablespace in `/opt/ts` is relocated to `./backup/ts`:

```
$ pg_basebackup -D backup/data -T /opt/ts=$(pwd)/backup/ts
```

To create a backup of the local server with one tar file for each tablespace compressed with `gzip` at level 9, stored in the directory `backup`:

```
$ pg_basebackup -D backup -Ft --compress=gzip:9
```

# pgbench

pgbench — run a benchmark test on PostgreSQL

## Synopsis

```
pgbench -i [option...] [dbname]
```

```
pgbench [option...] [dbname]
```

## Description

pgbench is a simple program for running benchmark tests on PostgreSQL. It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five `SELECT`, `UPDATE`, and `INSERT` commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

```
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 10
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
number of failed transactions: 0 (0.000%)
latency average = 11.013 ms
latency stddev = 7.351 ms
initial connection time = 45.758 ms
tps = 896.967014 (without initial connection time)
```

The first seven lines report some of the most important parameter settings. The sixth line reports the maximum number of tries for transactions with serialization or deadlock errors (see [Failures and Serialization/Deadlock Retries](#) for more information). The eighth line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions per client); these will be equal unless the run failed before completion or some SQL command(s) failed. (In `-T` mode, only the actual number of transactions is printed.) The next line reports the number of failed transactions due to serialization or deadlock errors (see [Failures and Serialization/Deadlock Retries](#) for more information). The last line reports the number of transactions per second.

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the `-i` (initialize) option to create and populate these tables. (When you are testing a custom script, you don't need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

```
pgbench -i [ other-options ] dbname
```

where *dbname* is the name of the already-created database to test in. (You may also need `-h`, `-p`, and/or `-U` options to specify how to connect to the database server.)

**Caution**

`pgbench -i` creates four tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

| table                         | # of rows |
|-------------------------------|-----------|
| -----                         | -----     |
| <code>pgbench_branches</code> | 1         |
| <code>pgbench_tellers</code>  | 10        |
| <code>pgbench_accounts</code> | 100000    |
| <code>pgbench_history</code>  | 0         |

You can (and, for most purposes, probably should) increase the number of rows by using the `-S` (scale factor) option. The `-F` (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn't include `-i`, that is

`pgbench [ options ] dbname`

In nearly all cases, you'll need some options to make a useful test. The most important options are `-c` (number of clients), `-t` (number of transactions), `-T` (time limit), and `-f` (specify a custom script file). See below for a full list.

## Options

The following is divided into three subsections. Different options are used during database initialization and while running benchmarks, but some options are useful in both cases.

### Initialization Options

`pgbench` accepts the following command-line initialization arguments:

`[-d] dbname`  
`[--dbname=]dbname`

Specifies the name of the database to test in. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

`-i`  
`--initialize`

Required to invoke initialization mode.

`-I init_steps`  
`--init-steps=init_steps`

Perform just a selected set of the normal initialization steps. *init\_steps* specifies the initialization steps to be performed, using one character per step. Each step is invoked in the specified order. The default is `dtgvp`. The available steps are:

**d** (Drop)

Drop any existing `pgbench` tables.

**t** (create Tables)

Create the tables used by the standard pgbench scenario, namely `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

**g** or **G** (Generate data, client-side or server-side)

Generate data and load it into the standard tables, replacing any data already present.

With **g** (client-side data generation), data is generated in `pgbench` client and then sent to the server. This uses the client/server bandwidth extensively through a `COPY`. `pgbench` uses the `FREEZE` option to load data into ordinary (non-partition) tables with version 14 or later of PostgreSQL to speed up subsequent `VACUUM`. Using **g** causes logging to print one message every 100,000 rows while generating data for all tables.

With **G** (server-side data generation), only small queries are sent from the `pgbench` client and then data is actually generated in the server. No significant bandwidth is required for this variant, but the server will do more work. Using **G** causes logging not to print any progress message while generating data.

The default initialization behavior uses client-side data generation (equivalent to **g**).

**v** (Vacuum)

Invoke `VACUUM` on the standard tables.

**p** (create Primary keys)

Create primary key indexes on the standard tables.

**f** (create Foreign keys)

Create foreign key constraints between the standard tables. (Note that this step is not performed by default.)

**-F** *fillfactor*  
**--fillfactor=***fillfactor*

Create the `pgbench_accounts`, `pgbench_tellers` and `pgbench_branches` tables with the given fillfactor. Default is 100.

**-n**  
**--no-vacuum**

Perform no vacuuming during initialization. (This option suppresses the **v** initialization step, even if it was specified in **-I**.)

**-q**  
**--quiet**

Switch logging to quiet mode, producing only one progress message per 5 seconds. The default logging prints one message each 100,000 rows, which often outputs many lines per second (especially on good hardware).

This setting has no effect if **G** is specified in **-I**.

**-s** *scale\_factor*  
**--scale=***scale\_factor*

Multiply the number of rows generated by the scale factor. For example, **-s 100** will create 10,000,000 rows in the `pgbench_accounts` table. Default is 1. When the scale is 20,000 or

larger, the columns used to hold account identifiers (**aid** columns) will switch to using larger integers (**bigint**), in order to be big enough to hold the range of account identifiers.

**--foreign-keys**

Create foreign key constraints between the standard tables. (This option adds the **f** step to the initialization step sequence, if it is not already present.)

**--index-tablespace=*index\_tablespace***

Create indexes in the specified tablespace, rather than the default tablespace.

**--partition-method=*NAME***

Create a partitioned **pgbench\_accounts** table with *NAME* method. Expected values are **range** or **hash**. This option requires that **--partitions** is set to non-zero. If unspecified, default is **range**.

**--partitions=*NUM***

Create a partitioned **pgbench\_accounts** table with *NUM* partitions of nearly equal size for the scaled number of accounts. Default is **0**, meaning no partitioning.

**--tablespace=*tablespace***

Create tables in the specified tablespace, rather than the default tablespace.

**--unlogged-tables**

Create all tables as unlogged tables, rather than permanent tables.

## Benchmarking Options

pgbench accepts the following command-line benchmarking arguments:

**-b *scriptname*[@*weight*]**

**--builtin=*scriptname*[@*weight*]**

Add the specified built-in script to the list of scripts to be executed. Available built-in scripts are: **tpcb-like**, **simple-update** and **select-only**. Unambiguous prefixes of built-in names are accepted. With the special name **list**, show the list of built-in scripts and exit immediately.

Optionally, write an integer weight after **@** to adjust the probability of selecting this script versus other ones. The default weight is **1**. See below for details.

**-c *clients***

**--client=*clients***

Number of clients simulated, that is, number of concurrent database sessions. Default is **1**.

**-C**

**--connect**

Establish a new connection for each transaction, rather than doing it just once per client session. This is useful to measure the connection overhead.

**-D *varname=value***

**--define=*varname=value***

Define a variable for use by a custom script (see below). Multiple **-D** options are allowed.

`-f filename[@weight]`  
`--file=filename[@weight]`

Add a transaction script read from *filename* to the list of scripts to be executed.

Optionally, write an integer weight after *@* to adjust the probability of selecting this script versus other ones. The default weight is 1. (To use a script file name that includes an *@* character, append a weight so that there is no ambiguity, for example *filen@me@1*.) See below for details.

`-j threads`  
`--jobs=threads`

Number of worker threads within pgbench. Using more than one thread can be helpful on multi-CPU machines. Clients are distributed as evenly as possible among available threads. Default is 1.

`-l`  
`--log`

Write information about each transaction to a log file. See below for details.

`-L limit`  
`--latency-limit=limit`

Transactions that last more than *limit* milliseconds are counted and reported separately, as *late*.

When throttling is used (`--rate=...`), transactions that lag behind schedule by more than *limit* ms, and thus have no hope of meeting the latency limit, are not sent to the server at all. They are counted and reported separately as *skipped*.

When the `--max-tries` option is used, a transaction which fails due to a serialization anomaly or from a deadlock will not be retried if the total time of all its tries is greater than *limit* ms. To limit only the time of tries and not their number, use `--max-tries=0`. By default, the option `--max-tries` is set to 1 and transactions with serialization/deadlock errors are not retried. See Failures and Serialization/Deadlock Retries for more information about retrying such transactions.

`-M querymode`  
`--protocol=querymode`

Protocol to use for submitting queries to the server:

- **simple**: use simple query protocol.
- **extended**: use extended query protocol.
- **prepared**: use extended query protocol with prepared statements.

In the **prepared** mode, pgbench reuses the parse analysis result starting from the second query iteration, so pgbench runs faster than in other modes.

The default is simple query protocol. (See Chapter 54 for more information.)

`-n`  
`--no-vacuum`

Perform no vacuuming before running the test. This option is *necessary* if you are running a custom test scenario that does not include the standard tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

`-N`  
`--skip-some-updates`

Run built-in simple-update script. Shorthand for `-b simple-update`.

**-P *sec***  
**--progress=*sec***

Show progress report every *sec* seconds. The report includes the time since the beginning of the run, the TPS since the last report, and the transaction latency average, standard deviation, and the number of failed transactions since the last report. Under throttling (**-R**), the latency is computed with respect to the transaction scheduled start time, not the actual transaction beginning time, thus it also includes the average schedule lag time. When **--max-tries** is used to enable transaction retries after serialization/deadlock errors, the report includes the number of retried transactions and the sum of all retries.

**-r**  
**--report-per-command**

Report the following statistics for each command after the benchmark finishes: the average per-statement latency (execution time from the perspective of the client), the number of failures, and the number of retries after serialization or deadlock errors in this command. The report displays retry statistics only if the **--max-tries** option is not equal to 1.

**-R *rate***  
**--rate=*rate***

Execute transactions targeting the specified rate instead of running as fast as possible (the default). The rate is given in transactions per second. If the targeted rate is above the maximum possible rate, the rate limit won't impact the results.

The rate is targeted by starting transactions along a Poisson-distributed schedule time line. The expected start time schedule moves forward based on when the client first started, not when the previous transaction ended. That approach means that when transactions go past their original scheduled end time, it is possible for later ones to catch up again.

When throttling is active, the transaction latency reported at the end of the run is calculated from the scheduled start times, so it includes the time each transaction had to wait for the previous transaction to finish. The wait time is called the schedule lag time, and its average and maximum are also reported separately. The transaction latency with respect to the actual transaction start time, i.e., the time spent executing the transaction in the database, can be computed by subtracting the schedule lag time from the reported latency.

If **--latency-limit** is used together with **--rate**, a transaction can lag behind so much that it is already over the latency limit when the previous transaction ends, because the latency is calculated from the scheduled start time. Such transactions are not sent to the server, but are skipped altogether and counted separately.

A high schedule lag time is an indication that the system cannot process transactions at the specified rate, with the chosen number of clients and threads. When the average transaction execution time is longer than the scheduled interval between each transaction, each successive transaction will fall further behind, and the schedule lag time will keep increasing the longer the test run is. When that happens, you will have to reduce the specified transaction rate.

**-s *scale\_factor***  
**--scale=*scale\_factor***

Report the specified scale factor in pgbench's output. With the built-in tests, this is not necessary; the correct scale factor will be detected by counting the number of rows in the **pgbench\_branches** table. However, when testing only custom benchmarks (**-f** option), the scale factor will be reported as 1 unless this option is used.

**-S**  
**--select-only**

Run built-in select-only script. Shorthand for **-b select-only**.

`-t transactions`  
`--transactions=transactions`

Number of transactions each client runs. Default is 10.

`-T seconds`  
`--time=seconds`

Run the test for this many seconds, rather than a fixed number of transactions per client. `-t` and `-T` are mutually exclusive.

`-v`  
`--vacuum-all`

Vacuum all four standard tables before running the test. With neither `-n` nor `-v`, `pgbench` will vacuum the `pgbench_tellers` and `pgbench_branches` tables, and will truncate `pgbench_history`.

`--aggregate-interval=seconds`

Length of aggregation interval (in seconds). May be used only with `-l` option. With this option, the log contains per-interval summary data, as described below.

`--exit-on-abort`

Exit immediately when any client is aborted due to some error. Without this option, even when a client is aborted, other clients could continue their run as specified by `-t` or `-T` option, and `pgbench` will print an incomplete results in this case.

Note that serialization failures or deadlock failures do not abort the client, so they are not affected by this option. See Failures and Serialization/Deadlock Retries for more information.

`--failures-detailed`

Report failures in per-transaction and aggregation logs, as well as in the main and per-script reports, grouped by the following types:

- serialization failures;
  - deadlock failures;
- See Failures and Serialization/Deadlock Retries for more information.

`--log-prefix=prefix`

Set the filename prefix for the log files created by `--log`. The default is `pgbench_log`.

`--max-tries=number_of_tries`

Enable retries for transactions with serialization/deadlock errors and set the maximum number of these tries. This option can be combined with the `--latency-limit` option which limits the total time of all transaction tries; moreover, you cannot use an unlimited number of tries (`--max-tries=0`) without `--latency-limit` or `--time`. The default value is 1 and transactions with serialization/deadlock errors are not retried. See Failures and Serialization/Deadlock Retries for more information about retrying such transactions.

`--progress-timestamp`

When showing progress (option `-P`), use a timestamp (Unix epoch) instead of the number of seconds since the beginning of the run. The unit is in seconds, with millisecond precision after the dot. This helps compare logs generated by various tools.

`--random-seed=seed`

Set random generator seed. Seeds the system random number generator, which then produces a sequence of initial generator states, one for each thread. Values for *seed* may be: *time* (the default, the seed is based on the current time), *rand* (use a strong random source, failing if none is available), or an unsigned decimal integer value. The random generator is invoked explicitly from a pgbench script (*random. . .* functions) or implicitly (for instance option `--rate` uses it to schedule transactions). When explicitly set, the value used for seeding is shown on the terminal. Any value allowed for *seed* may also be provided through the environment variable `PGBENCH_RANDOM_SEED`. To ensure that the provided seed impacts all possible uses, put this option first or use the environment variable.

Setting the seed explicitly allows to reproduce a pgbench run exactly, as far as random numbers are concerned. As the random state is managed per thread, this means the exact same pgbench run for an identical invocation if there is one client per thread and there are no external or data dependencies. From a statistical viewpoint reproducing runs exactly is a bad idea because it can hide the performance variability or improve performance unduly, e.g., by hitting the same pages as a previous run. However, it may also be of great help for debugging, for instance re-running a tricky case which leads to an error. Use wisely.

`--sampling-rate=rate`

Sampling rate, used when writing data into the log, to reduce the amount of log generated. If this option is given, only the specified fraction of transactions are logged. 1.0 means all transactions will be logged, 0.05 means only 5% of the transactions will be logged.

Remember to take the sampling rate into account when processing the log file. For example, when computing TPS values, you need to multiply the numbers accordingly (e.g., with 0.01 sample rate, you'll only get 1/100 of the actual TPS).

`--show-script=scriptname`

Show the actual code of builtin script *scriptname* on stderr, and exit immediately.

`--verbose-errors`

Print messages about all errors and failures (errors without retrying) including which limit for retries was exceeded and how far it was exceeded for the serialization/deadlock failures. (Note that in this case the output can be significantly increased.) See Failures and Serialization/Deadlock Retries for more information.

## Common Options

pgbench also accepts the following common command-line arguments for connection parameters and other common settings:

`--debug`

Print debugging output.

`-h hostname`

`--host=hostname`

The database server's host name

`-p port`

`--port=port`

The database server's port number

```
-U login
--username=login
```

The user name to connect as

```
-V
--version
```

Print the pgbench version and exit.

```
-?
--help
```

Show help about pgbench command line arguments, and exit.

## Exit Status

A successful run will exit with status 0. Exit status 1 indicates static problems such as invalid command-line options or internal errors which are supposed to never occur. Early errors that occur when starting benchmark such as initial connection failures also exit with status 1. Errors during the run such as database errors or problems in the script will result in exit status 2. In the latter case, pgbench will print partial results if `--exit-on-abort` option is not specified.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters.

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

### What Is the “Transaction” Actually Performed in pgbench?

pgbench executes test scripts chosen randomly from a specified list. The scripts may include built-in scripts specified with `-b` and user-provided scripts specified with `-f`. Each script may be given a relative weight specified after an `@` so as to change its selection probability. The default weight is 1. Scripts with a weight of 0 are ignored.

The default built-in transaction script (also invoked with `-b tpcb-like`) issues seven commands per transaction over randomly chosen `aid`, `tid`, `bid` and `delta`. The scenario is inspired by the TPC-B benchmark, but is not actually TPC-B, hence the name.

1. `BEGIN;`
2. `UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;`
3. `SELECT abalance FROM pgbench_accounts WHERE aid = :aid;`
4. `UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;`

5. UPDATE pgbench\_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
6. INSERT INTO pgbench\_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT\_TIMESTAMP);
7. END;

If you select the `simple-update` built-in (also `-N`), steps 4 and 5 aren't included in the transaction. This will avoid update contention on these tables, but it makes the test case even less like TPC-B.

If you select the `select-only` built-in (also `-S`), only the `SELECT` is issued.

## Custom Scripts

pgbench has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (`-f` option). In this case a “transaction” counts as one execution of a script file.

A script file contains one or more SQL commands terminated by semicolons. Empty lines and lines beginning with `--` are ignored. Script files can also contain “meta commands”, which are interpreted by pgbench itself, as described below.

### Note

Before PostgreSQL 9.6, SQL commands in script files were terminated by newlines, and so they could not be continued across lines. Now a semicolon is *required* to separate consecutive SQL commands (though an SQL command does not need one if it is followed by a meta command). If you need to create a script file that works with both old and new versions of pgbench, be sure to write each SQL command on a single line ending with a semicolon.

It is assumed that pgbench scripts do not contain incomplete blocks of SQL transactions. If at runtime the client reaches the end of the script without completing the last transaction block, it will be aborted.

There is a simple variable-substitution facility for script files. Variable names must consist of letters (including non-Latin letters), digits, and underscores, with the first character not being a digit. Variables can be set by the command-line `-D` option, explained above, or by the meta commands explained below. In addition to any variables preset by `-D` command-line options, there are a few variables that are preset automatically, listed in Table 301. A value specified for these variables using `-D` takes precedence over the automatic presets. Once set, a variable's value can be inserted into an SQL command by writing `:variablename`. When running more than one client session, each session has its own set of variables. pgbench supports up to 255 variable uses in one statement.

**Table 301. pgbench Automatic Variables**

| Variable                  | Description                                                         |
|---------------------------|---------------------------------------------------------------------|
| <code>client_id</code>    | unique number identifying the client session (starts from zero)     |
| <code>default_seed</code> | seed used in hash and pseudorandom permutation functions by default |
| <code>random_seed</code>  | random generator seed (unless overwritten with <code>-D</code> )    |
| <code>scale</code>        | current scale factor                                                |

Script file meta commands begin with a backslash (`\`) and normally extend to the end of the line, although they can be continued to additional lines by writing backslash-return. Arguments to a meta command are separated by white space. These meta commands are supported:

## `\gset [prefix] \aset [prefix]`

These commands may be used to end SQL queries, taking the place of the terminating semicolon (;).

When the `\gset` command is used, the preceding SQL query is expected to return one row, the columns of which are stored into variables named after column names, and prefixed with *prefix* if provided.

When the `\aset` command is used, all combined SQL queries (separated by `\;`) have their columns stored into variables named after column names, and prefixed with *prefix* if provided. If a query returns no row, no assignment is made and the variable can be tested for existence to detect this. If a query returns more than one row, the last value is kept.

`\gset` and `\aset` cannot be used in pipeline mode, since the query results are not yet available by the time the commands would need them.

The following example puts the final account balance from the first query into variable *abalance*, and fills variables *p\_two* and *p\_three* with integers from the third query. The result of the second query is discarded. The result of the two last combined queries are stored in variables *four* and *five*.

```
UPDATE pgbench_accounts
  SET abalance = abalance + :delta
  WHERE aid = :aid
  RETURNING abalance \gset
-- compound of two queries
SELECT 1 \;
SELECT 2 AS two, 3 AS three \gset p_
SELECT 4 AS four \; SELECT 5 AS five \aset
```

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks, similarly to `psql`'s `\if expression`. Conditional expressions are identical to those with `\set`, with non-zero values interpreted as true.

## `\set varname expression`

Sets variable *varname* to a value calculated from *expression*. The expression may contain the NULL constant, Boolean constants TRUE and FALSE, integer constants such as 5432, double constants such as 3.14159, references to variables *:variablename*, operators with their usual SQL precedence and associativity, function calls, SQL CASE generic conditional expressions and parentheses.

Functions and most operators return NULL on NULL input.

For conditional purposes, non zero numerical values are TRUE, zero numerical values and NULL are FALSE.

Too large or small integer and double constants, as well as integer arithmetic operators (+, -, \* and /) raise errors on overflows.

When no final ELSE clause is provided to a CASE, the default value is NULL.

Examples:

```
\set ntellers 10 * :scale
\set aid (1021 * random(1, 100000 * :scale)) % \
        (100000 * :scale) + 1
\set divx CASE WHEN :x <> 0 THEN :y/:x ELSE NULL END
```

```
\sleep number [ us | ms | s ]
```

Causes script execution to sleep for the specified duration in microseconds (us), milliseconds (ms) or seconds (s). If the unit is omitted then seconds are the default. *number* can be either an integer constant or a *:variablename* reference to a variable having an integer value.

Example:

```
\sleep 10 ms
```

```
\setshell varname command [ argument ... ]
```

Sets variable *varname* to the result of the shell command *command* with the given *argument*(s). The command must return an integer value through its standard output.

*command* and each *argument* can be either a text constant or a *:variablename* reference to a variable. If you want to use an *argument* starting with a colon, write an additional colon at the beginning of *argument*.

Example:

```
\setshell variable_to_be_assigned command
        literal_argument :variable ::literal_starting_with_colon
```

```
\shell command [ argument ... ]
```

Same as `\setshell`, but the result of the command is discarded.

Example:

```
\shell command
        literal_argument :variable ::literal_starting_with_colon
```

```
\startpipeline
\syncpipeline
\endpipeline
```

This group of commands implements pipelining of SQL statements. A pipeline must begin with a `\startpipeline` and end with an `\endpipeline`. In between there may be any number of `\syncpipeline` commands, which sends a sync message without ending the ongoing pipeline and flushing the send buffer. In pipeline mode, statements are sent to the server without waiting for the results of previous statements. See Section 32.5 for more details. Pipeline mode requires the use of extended query protocol.

## Built-in Operators

The arithmetic, bitwise, comparison and logical operators listed in Table 302 are built into pgbench and may be used in expressions appearing in `\set`. The operators are listed in increasing precedence order. Except as noted, operators taking two numeric inputs will produce a double value if either input is double, otherwise they produce an integer result.

**Table 302. pgbench Operators**

| <b>Operator</b>                                            | <b>Description</b>       | <b>Example(s)</b> |
|------------------------------------------------------------|--------------------------|-------------------|
| <i>boolean</i> OR <i>boolean</i> → <i>boolean</i>          | Logical OR               | 5 or 0 → TRUE     |
| <i>boolean</i> AND <i>boolean</i> → <i>boolean</i>         | Logical AND              | 3 and 0 → FALSE   |
| NOT <i>boolean</i> → <i>boolean</i>                        | Logical NOT              | not false → TRUE  |
| <i>boolean</i> IS [NOT] (NULL TRUE FALSE) → <i>boolean</i> | Boolean value tests      | 1 is null → FALSE |
| <i>value</i> ISNULL NOTNULL → <i>boolean</i>               | Nullness tests           | 1 notnull → TRUE  |
| <i>number</i> = <i>number</i> → <i>boolean</i>             | Equal                    | 5 = 4 → FALSE     |
| <i>number</i> <> <i>number</i> → <i>boolean</i>            | Not equal                | 5 <> 4 → TRUE     |
| <i>number</i> != <i>number</i> → <i>boolean</i>            | Not equal                | 5 != 5 → FALSE    |
| <i>number</i> < <i>number</i> → <i>boolean</i>             | Less than                | 5 < 4 → FALSE     |
| <i>number</i> <= <i>number</i> → <i>boolean</i>            | Less than or equal to    | 5 <= 4 → FALSE    |
| <i>number</i> > <i>number</i> → <i>boolean</i>             | Greater than             | 5 > 4 → TRUE      |
| <i>number</i> >= <i>number</i> → <i>boolean</i>            | Greater than or equal to | 5 >= 4 → TRUE     |
| <i>integer</i>   <i>integer</i> → <i>integer</i>           | Bitwise OR               | 1   2 → 3         |

| Operator                                  | Description                                                              | Example(s)                |
|-------------------------------------------|--------------------------------------------------------------------------|---------------------------|
| $integer \# integer \rightarrow integer$  | Bitwise XOR                                                              | $1 \# 3 \rightarrow 2$    |
| $integer \& integer \rightarrow integer$  | Bitwise AND                                                              | $1 \& 3 \rightarrow 1$    |
| $\sim integer \rightarrow integer$        | Bitwise NOT                                                              | $\sim 1 \rightarrow -2$   |
| $integer \ll integer \rightarrow integer$ | Bitwise shift left                                                       | $1 \ll 2 \rightarrow 4$   |
| $integer \gg integer \rightarrow integer$ | Bitwise shift right                                                      | $8 \gg 2 \rightarrow 2$   |
| $number + number \rightarrow number$      | Addition                                                                 | $5 + 4 \rightarrow 9$     |
| $number - number \rightarrow number$      | Subtraction                                                              | $3 - 2.0 \rightarrow 1.0$ |
| $number * number \rightarrow number$      | Multiplication                                                           | $5 * 4 \rightarrow 20$    |
| $number / number \rightarrow number$      | Division (truncates the result towards zero if both inputs are integers) | $5 / 3 \rightarrow 1$     |
| $integer \% integer \rightarrow integer$  | Modulo (remainder)                                                       | $3 \% 2 \rightarrow 1$    |
| $- number \rightarrow number$             | Negation                                                                 | $- 2.0 \rightarrow -2.0$  |

## Built-In Functions

The functions listed in Table 303 are built into pgbench and may be used in expressions appearing in `\set`.

**Table 303. pgbench Functions**

| Function                                      | Description                                                                                         | Example(s)                                                 |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <code>abs ( number )</code>                   | → same type as input<br>Absolute value                                                              | <code>abs( -17 ) → 17</code>                               |
| <code>debug ( number )</code>                 | → same type as input<br>Prints the argument to stderr, and returns the argument.                    | <code>debug( 5432.1 ) → 5432.1</code>                      |
| <code>double ( number )</code>                | → double<br>Casts to double.                                                                        | <code>double(5432) → 5432.0</code>                         |
| <code>exp ( number )</code>                   | → double<br>Exponential (e raised to the given power)                                               | <code>exp(1.0) → 2.718281828459045</code>                  |
| <code>greatest ( number [, ... ] )</code>     | → double if any argument is double, else integer<br>Selects the largest value among the arguments.  | <code>greatest(5, 4, 3, 2) → 5</code>                      |
| <code>hash ( value [, seed ] )</code>         | → integer<br>This is an alias for <code>hash_murmur2</code> .                                       | <code>hash(10, 5432) → -5817877081768721676</code>         |
| <code>hash_fnv1a ( value [, seed ] )</code>   | → integer<br>Computes FNV-1a hash <sup>1</sup> .                                                    | <code>hash_fnv1a(10, 5432) → -7793829335365542153</code>   |
| <code>hash_murmur2 ( value [, seed ] )</code> | → integer<br>Computes MurmurHash2 hash <sup>2</sup> .                                               | <code>hash_murmur2(10, 5432) → -5817877081768721676</code> |
| <code>int ( number )</code>                   | → integer<br>Casts to integer.                                                                      | <code>int(5.4 + 3.8) → 9</code>                            |
| <code>least ( number [, ... ] )</code>        | → double if any argument is double, else integer<br>Selects the smallest value among the arguments. | <code>least(5, 4, 3, 2.1) → 2.1</code>                     |
| <code>ln ( number )</code>                    | → double<br>Natural logarithm                                                                       | <code>ln(2.718281828459045) → 1.0</code>                   |
| <code>mod ( integer, integer )</code>         | → integer<br>Modulo (remainder)                                                                     | <code>mod(54, 32) → 22</code>                              |
| <code>permute ( i, size [, seed ] )</code>    | → integer                                                                                           |                                                            |

| Function                                                                                       | Description                                                                                                                                                                                                                           | Example(s)                                                                       |
|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
|                                                                                                | Permuted value of $i$ , in the range $[0, \text{size})$ . This is the new position of $i$ (modulo $\text{size}$ ) in a pseudorandom permutation of the integers $0 \dots \text{size}-1$ , parameterized by $\text{seed}$ , see below. | $\text{permute}(0, 4) \rightarrow$ an integer between 0 and 3                    |
| $\text{pi}() \rightarrow \text{double}$                                                        | Approximate value of $\pi$                                                                                                                                                                                                            | $\text{pi}() \rightarrow 3.14159265358979323846$                                 |
| $\text{pow}(x, y) \rightarrow \text{double}$<br>$\text{power}(x, y) \rightarrow \text{double}$ | $x$ raised to the power of $y$                                                                                                                                                                                                        | $\text{pow}(2.0, 10) \rightarrow 1024.0$                                         |
| $\text{random}(lb, ub) \rightarrow \text{integer}$                                             | Computes a uniformly-distributed random integer in $[lb, ub]$ .                                                                                                                                                                       | $\text{random}(1, 10) \rightarrow$ an integer between 1 and 10                   |
| $\text{random\_exponential}(lb, ub, \text{parameter}) \rightarrow \text{integer}$              | Computes an exponentially-distributed random integer in $[lb, ub]$ , see below.                                                                                                                                                       | $\text{random\_exponential}(1, 10, 3.0) \rightarrow$ an integer between 1 and 10 |
| $\text{random\_gaussian}(lb, ub, \text{parameter}) \rightarrow \text{integer}$                 | Computes a Gaussian-distributed random integer in $[lb, ub]$ , see below.                                                                                                                                                             | $\text{random\_gaussian}(1, 10, 2.5) \rightarrow$ an integer between 1 and 10    |
| $\text{random\_zipfian}(lb, ub, \text{parameter}) \rightarrow \text{integer}$                  | Computes a Zipfian-distributed random integer in $[lb, ub]$ , see below.                                                                                                                                                              | $\text{random\_zipfian}(1, 10, 1.5) \rightarrow$ an integer between 1 and 10     |
| $\text{sqrt}(\text{number}) \rightarrow \text{double}$                                         | Square root                                                                                                                                                                                                                           | $\text{sqrt}(2.0) \rightarrow 1.414213562$                                       |

The `random` function generates values using a uniform distribution, that is all the values are drawn within the specified range with equal probability. The `random_exponential`, `random_gaussian` and `random_zipfian` functions require an additional double parameter which determines the precise shape of the distribution.

- For an exponential distribution, *parameter* controls the distribution by truncating a quickly-decreasing exponential distribution at *parameter*, and then projecting onto integers between the bounds. To be precise, with

$$f(x) = \exp(-\text{parameter} * (x - \min) / (\max - \min + 1)) / (1 - \exp(-\text{parameter}))$$

Then value  $i$  between *min* and *max* inclusive is drawn with probability:  $f(i) - f(i + 1)$ .

Intuitively, the larger the *parameter*, the more frequently values close to *min* are accessed, and the less frequently values close to *max* are accessed. The closer to 0 *parameter* is, the flatter (more uniform) the access distribution. A crude approximation of the distribution is that the most frequent 1% values in the range, close to *min*, are drawn *parameter*% of the time. The *parameter* value must be strictly positive.

- For a Gaussian distribution, the interval is mapped onto a standard normal distribution (the classical bell-shaped Gaussian curve) truncated at `-parameter` on the left and `+parameter` on the right. Values in the middle of the interval are more likely to be drawn. To be precise, if  $\text{PHI}(x)$  is the cumulative distribution function of the standard normal distribution, with mean  $\mu$  defined as  $(\text{max} + \text{min}) / 2.0$ , with

$$f(x) = \frac{\text{PHI}(2.0 * \text{parameter} * (x - \mu) / (\text{max} - \text{min} + 1))}{(2.0 * \text{PHI}(\text{parameter}) - 1)}$$

then value  $i$  between  $\text{min}$  and  $\text{max}$  inclusive is drawn with probability:  $f(i + 0.5) - f(i - 0.5)$ . Intuitively, the larger the *parameter*, the more frequently values close to the middle of the interval are drawn, and the less frequently values close to the *min* and *max* bounds. About 67% of values are drawn from the middle  $1.0 / \text{parameter}$ , that is a relative  $0.5 / \text{parameter}$  around the mean, and 95% in the middle  $2.0 / \text{parameter}$ , that is a relative  $1.0 / \text{parameter}$  around the mean; for instance, if *parameter* is 4.0, 67% of values are drawn from the middle quarter ( $1.0 / 4.0$ ) of the interval (i.e., from  $3.0 / 8.0$  to  $5.0 / 8.0$ ) and 95% from the middle half ( $2.0 / 4.0$ ) of the interval (second and third quartiles). The minimum allowed *parameter* value is 2.0.

- `random_zipfian` generates a bounded Zipfian distribution. *parameter* defines how skewed the distribution is. The larger the *parameter*, the more frequently values closer to the beginning of the interval are drawn. The distribution is such that, assuming the range starts from 1, the ratio of the probability of drawing  $k$  versus drawing  $k+1$  is  $((k+1)/k) ** \text{parameter}$ . For example, `random_zipfian(1, ..., 2.5)` produces the value 1 about  $(2/1) ** 2.5 = 5.66$  times more frequently than 2, which itself is produced  $(3/2) ** 2.5 = 2.76$  times more frequently than 3, and so on.

pgbench's implementation is based on "Non-Uniform Random Variate Generation", Luc Devroye, p. 550-551, Springer 1986. Due to limitations of that algorithm, the *parameter* value is restricted to the range [1.001, 1000].

### Note

When designing a benchmark which selects rows non-uniformly, be aware that the rows chosen may be correlated with other data such as IDs from a sequence or the physical row ordering, which may skew performance measurements.

To avoid this, you may wish to use the `permute` function, or some other additional step with similar effect, to shuffle the selected rows and remove such correlations.

Hash functions `hash`, `hash_murmur2` and `hash_fnv1a` accept an input value and an optional seed parameter. In case the seed isn't provided the value of `:default_seed` is used, which is initialized randomly unless set by the command-line `-D` option.

`permute` accepts an input value, a size, and an optional seed parameter. It generates a pseudorandom permutation of integers in the range  $[0, \text{size})$ , and returns the index of the input value in the permuted values. The permutation chosen is parameterized by the seed, which defaults to `:default_seed`, if not specified. Unlike the hash functions, `permute` ensures that there are no collisions or holes in the output values. Input values outside the interval are interpreted modulo the size. The function raises an error if the size is not positive. `permute` can be used to scatter the distribution of non-uniform random functions such as `random_zipfian` or `random_exponential` so that values drawn more often are not trivially correlated. For instance, the following pgbench script simulates a possible real world workload typical for social media and blogging platforms where a few accounts generate excessive load:

```
\set size 1000000
\set r random_zipfian(1, :size, 1.07)
\set k 1 + permute(:r, :size)
```

In some cases several distinct distributions are needed which don't correlate with each other and this is when the optional seed parameter comes in handy:

```
\set k1 1 + permute(:r, :size, :default_seed + 123)
\set k2 1 + permute(:r, :size, :default_seed + 321)
```

A similar behavior can also be approximated with hash:

```
\set size 1000000
\set r random_zipfian(1, 100 * :size, 1.07)
\set k 1 + abs(hash(:r)) % :size
```

However, since `hash` generates collisions, some values will not be reachable and others will be more frequent than expected from the original distribution.

As an example, the full definition of the built-in TPC-B-like transaction is:

```
\set aid random(1, 100000 * :scale)
\set bid random(1, 1 * :scale)
\set tid random(1, 10 * :scale)
\set delta random(-5000, 5000)
BEGIN;
UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid
= :aid;
SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid
= :tid;
UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid
= :bid;
INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;
```

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it's important for each client session to have its own variables — otherwise they'd not be independently touching different rows.)

## Per-Transaction Logging

With the `-l` option (but without the `--aggregate-interval` option), `pgbench` writes information about each transaction to a log file. The log file will be named *prefix.nnn*, where *prefix* defaults to `pgbench_log`, and *nnn* is the PID of the `pgbench` process. The prefix can be changed by using the `--log-prefix` option. If the `-j` option is 2 or higher, so that there are multiple worker threads, each will have its own log file. The first worker will use the same name for its log file as in the standard single worker case. The additional log files for the other workers will be named *pre-fix.nnn.mmm*, where *mmm* is a sequential number for each worker starting with 1.

Each line in a log file describes one transaction. It contains the following space-separated fields:

*client\_id*

identifies the client session that ran the transaction

*transaction\_no*

counts how many transactions have been run by that session

*time*

transaction's elapsed time, in microseconds

*script\_no*

identifies the script file that was used for the transaction (useful when multiple scripts are specified with `-f` or `-b`)

*time\_epoch*

transaction's completion time, as a Unix-epoch time stamp

*time\_us*

fractional-second part of transaction's completion time, in microseconds

*schedule\_lag*

transaction start delay, that is the difference between the transaction's scheduled start time and the time it actually started, in microseconds (present only if `--rate` is specified)

*retries*

count of retries after serialization or deadlock errors during the transaction (present only if `--max-tries` is not equal to one)

When both `--rate` and `--latency-limit` are used, the *time* for a skipped transaction will be reported as `skipped`. If the transaction ends with a failure, its *time* will be reported as `failed`. If you use the `--failures-detailed` option, the *time* of the failed transaction will be reported as `serialization` or `deadlock` depending on the type of failure (see Failures and Serialization/Deadlock Retries for more information).

Here is a snippet of a log file generated in a single-client run:

```
0 199 2241 0 1175850568 995598
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663
```

Another example with `--rate=100` and `--latency-limit=5` (note the additional *schedule\_lag* column):

```
0 81 4621 0 1412881037 912698 3005
0 82 6173 0 1412881037 914578 4304
0 83 skipped 0 1412881037 914578 5217
0 83 skipped 0 1412881037 914578 5099
0 83 4722 0 1412881037 916203 3108
0 84 4142 0 1412881037 918023 2333
0 85 2465 0 1412881037 919759 740
```

In this example, transaction 82 was late, because its latency (6.173 ms) was over the 5 ms limit. The next two transactions were skipped, because they were already late before they were even started.

The following example shows a snippet of a log file with failures and retries, with the maximum number of tries set to 10 (note the additional *retries* column):

```
3 0 47423 0 1499414498 34501 3
3 1 8333 0 1499414498 42848 0
3 2 8358 0 1499414498 51219 0
4 0 72345 0 1499414498 59433 6
1 3 41718 0 1499414498 67879 4
1 4 8416 0 1499414498 76311 0
3 3 33235 0 1499414498 84469 3
0 0 failed 0 1499414498 84905 9
2 0 failed 0 1499414498 86248 9
3 4 8307 0 1499414498 92788 0
```

If the `--failures-detailed` option is used, the type of failure is reported in the *time* like this:

```
3 0 47423 0 1499414498 34501 3
3 1 8333 0 1499414498 42848 0
3 2 8358 0 1499414498 51219 0
4 0 72345 0 1499414498 59433 6
1 3 41718 0 1499414498 67879 4
1 4 8416 0 1499414498 76311 0
3 3 33235 0 1499414498 84469 3
0 0 serialization 0 1499414498 84905 9
2 0 serialization 0 1499414498 86248 9
3 4 8307 0 1499414498 92788 0
```

When running a long test on hardware that can handle a lot of transactions, the log files can become very large. The `--sampling-rate` option can be used to log only a random sample of transactions.

## Aggregated Logging

With the `--aggregate-interval` option, a different format is used for the log files. Each log line describes one aggregation interval. It contains the following space-separated fields:

*interval\_start*

start time of the interval, as a Unix-epoch time stamp

*num\_transactions*

number of transactions within the interval

*sum\_latency*

sum of transaction latencies

*sum\_latency\_2*

sum of squares of transaction latencies

*min\_latency*

minimum transaction latency

*max\_latency*

maximum transaction latency

*sum\_lag*

sum of transaction start delays (zero unless `--rate` is specified)

*sum\_lag\_2*

sum of squares of transaction start delays (zero unless `--rate` is specified)

*min\_lag*

minimum transaction start delay (zero unless `--rate` is specified)

*max\_lag*

maximum transaction start delay (zero unless `--rate` is specified)

*skipped*

number of transactions skipped because they would have started too late (zero unless `--rate` and `--latency-limit` are specified)

*retried*

number of retried transactions (zero unless `--max-tries` is not equal to one)

*retries*

number of retries after serialization or deadlock errors (zero unless `--max-tries` is not equal to one)

*serialization\_failures*

number of transactions that got a serialization error and were not retried afterwards (zero unless `--failures-detailed` is specified)

*deadlock\_failures*

number of transactions that got a deadlock error and were not retried afterwards (zero unless `--failures-detailed` is specified)

Here is some example output generated with this option:

```
pgbench --aggregate-interval=10 --time=20 --client=10 --log --  
rate=1000 --latency-limit=10 --failures-detailed --max-tries=10  
test
```

```
1650260552 5178 26171317 177284491527 1136 44462 2647617 7321113867  
0 9866 64 7564 28340 4148 0  
1650260562 4808 25573984 220121792172 1171 62083 3037380 9666800914  
0 9998 598 7392 26621 4527 0
```

Notice that while the plain (unaggregated) log format shows which script was used for each transaction, the aggregated format does not. Therefore if you need per-script data, you need to aggregate the data on your own.

## Per-Statement Report

With the `-r` option, `pgbench` collects the following statistics for each statement:

- **latency** — elapsed transaction time for each statement. `pgbench` reports an average value of all successful runs of the statement.
- The number of failures in this statement. See Failures and Serialization/Deadlock Retries for more information.

- The number of retries after a serialization or a deadlock error in this statement. See Failures and Serialization/Deadlock Retries for more information.

The report displays retry statistics only if the `--max-tries` option is not equal to 1.

All values are computed for each statement executed by every client and are reported after the benchmark has finished.

For the default script, the output will look similar to this:

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
number of failed transactions: 0 (0.000%)
number of transactions above the 50.0 ms latency limit: 1311/10000
(13.110 %)
latency average = 28.488 ms
latency stddev = 21.009 ms
initial connection time = 69.068 ms
tps = 346.224794 (without initial connection time)
statement latencies in milliseconds and failures:
  0.012  0  \set aid random(1, 100000 * :scale)
  0.002  0  \set bid random(1, 1 * :scale)
  0.002  0  \set tid random(1, 10 * :scale)
  0.002  0  \set delta random(-5000, 5000)
  0.319  0  BEGIN;
  0.834  0  UPDATE pgbench_accounts SET abalance = abalance
+ :delta WHERE aid = :aid;
  0.641  0  SELECT abalance FROM pgbench_accounts WHERE aid
= :aid;
 11.126  0  UPDATE pgbench_tellers SET tbalance = tbalance
+ :delta WHERE tid = :tid;
 12.961  0  UPDATE pgbench_branches SET bbalance = bbalance
+ :delta WHERE bid = :bid;
  0.634  0  INSERT INTO pgbench_history (tid, bid, aid, delta,
mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
  1.957  0  END;
```

Another example of output for the default script using serializable default transaction isolation level (`PGOPTIONS='-c default_transaction_isolation=serializable'` `pgbench ...`):

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 10
number of transactions per client: 1000
number of transactions actually processed: 6317/10000
```

```
number of failed transactions: 3683 (36.830%)
number of transactions retried: 7667 (76.670%)
total number of retries: 45339
number of transactions above the 50.0 ms latency limit: 106/6317
(1.678 %)
latency average = 17.016 ms
latency stddev = 13.283 ms
initial connection time = 45.017 ms
tps = 186.792667 (without initial connection time)
statement latencies in milliseconds, failures and retries:
 0.006      0      0 \set aid random(1, 100000 * :scale)
 0.001      0      0 \set bid random(1, 1 * :scale)
 0.001      0      0 \set tid random(1, 10 * :scale)
 0.001      0      0 \set delta random(-5000, 5000)
 0.385      0      0 BEGIN;
 0.773      0      1 UPDATE pgbench_accounts SET abalance =
abalance + :delta WHERE aid = :aid;
 0.624      0      0 SELECT abalance FROM pgbench_accounts WHERE
aid = :aid;
 1.098    320    3762 UPDATE pgbench_tellers SET tbalance =
tbalance + :delta WHERE tid = :tid;
 0.582   3363   41576 UPDATE pgbench_branches SET bbalance =
bbalance + :delta WHERE bid = :bid;
 0.465      0      0 INSERT INTO pgbench_history (tid,
bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta,
CURRENT_TIMESTAMP);
 1.933      0      0 END;
```

If multiple script files are specified, all statistics are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.

## Failures and Serialization/Deadlock Retries

When executing pgbench, there are three main types of errors:

- Errors of the main program. They are the most serious and always result in an immediate exit from pgbench with the corresponding error message. They include:
  - errors at the beginning of pgbench (e.g. an invalid option value);
  - errors in the initialization mode (e.g. the query to create tables for built-in scripts fails);
  - errors before starting threads (e.g. could not connect to the database server, syntax error in the meta command, thread creation failure);
  - internal pgbench errors (which are supposed to never occur...).
- Errors when the thread manages its clients (e.g. the client could not start a connection to the database server / the socket for connecting the client to the database server has become invalid). In such cases all clients of this thread stop while other threads continue to work. However, `--exit-on-abort` is specified, all of the threads stop immediately in this case.
- Direct client errors. They lead to immediate exit from pgbench with the corresponding error message in the case of an internal pgbench error (which are supposed to never occur...) or when `--`

`exit-on-abort` is specified. Otherwise in the worst case they only lead to the abortion of the failed client while other clients continue their run (but some client errors are handled without an abortion of the client and reported separately, see below). Later in this section it is assumed that the discussed errors are only the direct client errors and they are not internal pgbench errors.

A client's run is aborted in case of a serious error; for example, the connection with the database server was lost or the end of script was reached without completing the last transaction. In addition, if execution of an SQL or meta command fails for reasons other than serialization or deadlock errors, the client is aborted. Otherwise, if an SQL command fails with serialization or deadlock errors, the client is not aborted. In such cases, the current transaction is rolled back, which also includes setting the client variables as they were before the run of this transaction (it is assumed that one transaction script contains only one transaction; see What Is the "Transaction" Actually Performed in pgbench? for more information). Transactions with serialization or deadlock errors are repeated after rollbacks until they complete successfully or reach the maximum number of tries (specified by the `--max-tries` option) / the maximum time of retries (specified by the `--latency-limit` option) / the end of benchmark (specified by the `--time` option). If the last trial run fails, this transaction will be reported as failed but the client is not aborted and continues to work.

### Note

Without specifying the `--max-tries` option, a transaction will never be retried after a serialization or deadlock error because its default value is 1. Use an unlimited number of tries (`--max-tries=0`) and the `--latency-limit` option to limit only the maximum time of tries. You can also use the `--time` option to limit the benchmark duration under an unlimited number of tries.

Be careful when repeating scripts that contain multiple transactions: the script is always retried completely, so successful transactions can be performed several times.

Be careful when repeating transactions with shell commands. Unlike the results of SQL commands, the results of shell commands are not rolled back, except for the variable value of the `\setshell` command.

The latency of a successful transaction includes the entire time of transaction execution with rollbacks and retries. The latency is measured only for successful transactions and commands but not for failed transactions or commands.

The main report contains the number of failed transactions. If the `--max-tries` option is not equal to 1, the main report also contains statistics related to retries: the total number of retried transactions and total number of retries. The per-script report inherits all these fields from the main report. The per-statement report displays retry statistics only if the `--max-tries` option is not equal to 1.

If you want to group failures by basic types in per-transaction and aggregation logs, as well as in the main and per-script reports, use the `--failures-detailed` option. If you also want to distinguish all errors and failures (errors without retrying) by type including which limit for retries was exceeded and how much it was exceeded by for the serialization/deadlock failures, use the `--verbose-errors` option.

## Table Access Methods

You may specify the Table Access Method for the pgbench tables. The environment variable `PGOPTIONS` specifies database configuration options that are passed to PostgreSQL via the command line (See Section 19.1.4). For example, a hypothetical default Table Access Method for the tables that pgbench creates called `wuzza` can be specified with:

```
PGOPTIONS='-c default_table_access_method=wuzza'
```

## Good Practices

It is very easy to use pgbench to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, *never* believe any test that runs for only a few seconds. Use the `-t` or `-T` option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It's a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (`-s`) should be at least as large as the largest number of clients you intend to test (`-c`); else you'll mostly be measuring update contention. There are only `-s` rows in the `pgbench_branches` table, and every transaction wants to update one of them, so `-c` values in excess of `-s` will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it's been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If autovacuum is enabled it can result in unpredictable changes in measured performance.

A limitation of pgbench is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running pgbench on a different machine from the database server, although low network latency will be essential. It might even be useful to run several pgbench instances concurrently, on several client machines, against the same database server.

## Security

If untrusted users have access to a database that has not adopted a secure schema usage pattern, do not run pgbench in that database. pgbench uses unqualified names and does not manipulate the search path.

---

# pg\_combinebackup

pg\_combinebackup — reconstruct a full backup from an incremental backup and dependent backups

## Synopsis

pg\_combinebackup [*option...*] [*backup\_directory...*]

## Description

pg\_combinebackup is used to reconstruct a synthetic full backup from an incremental backup and the earlier backups upon which it depends.

Specify all of the required backups on the command line from oldest to newest. That is, the first backup directory should be the path to the full backup, and the last should be the path to the final incremental backup that you wish to restore. The reconstructed backup will be written to the output directory specified by the `-O` option.

pg\_combinebackup will attempt to verify that the backups you specify form a legal backup chain from which a correct full backup can be reconstructed. However, it is not designed to help you keep track of which backups depend on which other backups. If you remove one or more of the previous backups upon which your incremental backup relies, you will not be able to restore it. Moreover, pg\_combinebackup only attempts to verify that the backups have the correct relationship to each other, not that each individual backup is intact; for that, use pg\_verifybackup.

Since the output of pg\_combinebackup is a synthetic full backup, it can be used as an input to a future invocation of pg\_combinebackup. The synthetic full backup would be specified on the command line in lieu of the chain of backups from which it was reconstructed.

## Options

`-d`  
`--debug`

Print lots of debug logging output on `stderr`.

`-k`  
`--link`

Use hard links instead of copying files to the synthetic backup. Reconstruction of the synthetic backup might be faster (no file copying) and use less disk space, but care must be taken when using the output directory, because any modifications to that directory (for example, starting the server) can also affect the input directories. Likewise, changes to the input directories (for example, starting the server on the full backup) could affect the output directory. Thus, this option is best used when the input directories are only copies that will be removed after pg\_combinebackup has completed.

Requires that the input backups and the output directory are in the same file system.

If a backup manifest is not available or does not contain checksum of the right type, hard links will still be created, but the file will be also read block-by-block for the checksum calculation.

`-n`  
`--dry-run`

The `-n/--dry-run` option instructs pg\_combinebackup to figure out what would be done without actually creating the target directory or any output files. It is particularly useful in combination with `--debug`.

-N

--no-sync

By default, `pg_combinebackup` will wait for all files to be written safely to disk. This option causes `pg_combinebackup` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the output backup corrupt. Generally, this option is useful for testing but should not be used when creating a production installation.

-o *outputdir*

--output=*outputdir*

Specifies the output directory to which the synthetic full backup should be written. Currently, this argument is required.

-T *olddir=newdir*

--tablespace-mapping=*olddir=newdir*

Relocates the tablespace in directory *olddir* to *newdir* during the backup. *olddir* is the absolute path of the tablespace as it exists in the final backup specified on the command line, and *newdir* is the absolute path to use for the tablespace in the reconstructed backup. If either path needs to contain an equal sign (=), precede that with a backslash. This option can be specified multiple times for multiple tablespaces.

--clone

Use efficient file cloning (also known as “reflinks” on some systems) instead of copying files to the new data directory, which can result in near-instantaneous copying of the data files.

If a backup manifest is not available or does not contain checksum of the right type, file cloning will be used to copy the file, but the file will be also read block-by-block for the checksum calculation.

File cloning is only supported on some operating systems and file systems. If it is selected but not supported, the `pg_combinebackup` run will error. At present, it is supported on Linux (kernel 4.5 or later) with Btrfs and XFS (on file systems created with reflink support), and on macOS with APFS.

--copy

Perform regular file copy. This is the default. (See also `--copy-file-range`, `--clone`, and `-k/--link`.)

--copy-file-range

Use the `copy_file_range` system call for efficient copying. On some file systems this gives results similar to `--clone`, sharing physical disk blocks, while on others it may still copy blocks, but do so via an optimized path. At present, it is supported on Linux and FreeBSD.

If a backup manifest is not available or does not contain checksum of the right type, `copy_file_range` will be used to copy the file, but the file will be also read block-by-block for the checksum calculation.

--manifest-checksums=*algorithm*

Like `pg_basebackup`, `pg_combinebackup` writes a backup manifest in the output directory. This option specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are NONE, CRC32C, SHA224, SHA256, SHA384, and SHA512. The default is CRC32C.

--no-manifest

Disables generation of a backup manifest. If this option is not specified, a backup manifest for the reconstructed backup will be written to the output directory.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_combinebackup` will recursively open and synchronize all files in the backup directory. When the plain format is used, the search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file system that contains the backup directory. When the plain format is used, `pg_combinebackup` will also synchronize the file systems that contain the WAL files and each tablespace. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-V`

`--version`

Prints the `pg_combinebackup` version and exits.

`-?`

`--help`

Shows help about `pg_combinebackup` command line arguments, and exits.

## Limitations

`pg_combinebackup` does not recompute page checksums when writing the output directory. Therefore, if any of the backups used for reconstruction were taken with checksums disabled, but the final backup was taken with checksums enabled, the resulting directory may contain pages with invalid checksums.

To avoid this problem, taking a new full backup after changing the checksum state of the cluster using `pg_checksums` is recommended. Otherwise, you can disable and then optionally reenables checksums on the directory produced by `pg_combinebackup` in order to correct the problem.

## Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by `libpq` (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

# pg\_config

pg\_config — retrieve information about the installed version of PostgreSQL

## Synopsis

pg\_config [*option...*]

## Description

The `pg_config` utility prints configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries.

## Options

To use `pg_config`, supply one or more of the following options:

`--bindir`

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

`--docdir`

Print the location of documentation files.

`--htmldir`

Print the location of HTML documentation files.

`--includedir`

Print the location of C header files of the client interfaces.

`--pkgincludedir`

Print the location of other C header files.

`--includedir-server`

Print the location of C header files for server programming.

`--libdir`

Print the location of object code libraries.

`--pkglibdir`

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)

`--localedir`

Print the location of locale support files. (This will be an empty string if locale support was not configured when PostgreSQL was built.)

**--mandir**

Print the location of manual pages.

**--sharedir**

Print the location of architecture-independent support files.

**--sysconfdir**

Print the location of system-wide configuration files.

**--pgxs**

Print the location of extension makefiles.

**--configure**

Print the options that were given to the `configure` script when PostgreSQL was configured for building. This can be used to reproduce the identical configuration, or to find out with what options a binary package was built. (Note however that binary packages often contain vendor-specific custom patches.) See also the examples below.

**--cc**

Print the value of the `CC` variable that was used for building PostgreSQL. This shows the C compiler used.

**--cppflags**

Print the value of the `CPPFLAGS` variable that was used for building PostgreSQL. This shows C compiler switches needed at preprocessing time (typically, `-I` switches).

**--cflags**

Print the value of the `CFLAGS` variable that was used for building PostgreSQL. This shows C compiler switches.

**--cflags\_sl**

Print the value of the `CFLAGS_SL` variable that was used for building PostgreSQL. This shows extra C compiler switches used for building shared libraries.

**--ldflags**

Print the value of the `LDFLAGS` variable that was used for building PostgreSQL. This shows linker switches.

**--ldflags\_ex**

Print the value of the `LDFLAGS_EX` variable that was used for building PostgreSQL. This shows linker switches used for building executables only.

**--ldflags\_sl**

Print the value of the `LDFLAGS_SL` variable that was used for building PostgreSQL. This shows linker switches used for building shared libraries only.

**--libs**

Print the value of the `LIBS` variable that was used for building PostgreSQL. This normally contains `-l` switches for external libraries linked into PostgreSQL.

**--version**

Print the version of PostgreSQL.

**-?****--help**

Show help about pg\_config command line arguments, and exit.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

## Notes

The options `--docdir`, `--pkgincludedir`, `--localedir`, `--mandir`, `--sharedir`, `--sysconfdir`, `--cc`, `--cppflags`, `--cflags`, `--cflags_sl`, `--ldflags`, `--ldflags_sl`, and `--libs` were added in PostgreSQL 8.1. The option `--htmldir` was added in PostgreSQL 8.4. The option `--ldflags_ex` was added in PostgreSQL 9.0.

## Example

To reproduce the build configuration of the current PostgreSQL installation, run the following command:

```
eval `./configure `pg_config --configure`
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

---

# pg\_dump

pg\_dump — export a PostgreSQL database as an SQL script or to other formats

## Synopsis

pg\_dump [*connection-option...*] [*option...*] [*dbname*]

## Description

pg\_dump is a utility for exporting a PostgreSQL database. It makes consistent exports even if the database is being used concurrently. pg\_dump does not block other users accessing the database (readers or writers). Note, however, that except in simple cases, pg\_dump is generally not the right choice for taking regular backups of production databases. See Chapter 25 for further discussion.

pg\_dump only dumps a single database. To export an entire cluster, or to export global objects that are common to all databases in a cluster (such as roles and tablespaces), use pg\_dumpall.

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to psql. Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications, even on other SQL database products.

The alternative archive file formats must be used with pg\_restore to rebuild the database. They allow pg\_restore to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with pg\_restore, pg\_dump provides a flexible archival and transfer mechanism. pg\_dump can be used to export an entire database, then pg\_restore can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the “custom” format (-Fc) and the “directory” format (-Fd). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The “directory” format is the only format that supports parallel dumps.

While running pg\_dump, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

### Warning

Restoring a dump causes the destination to execute arbitrary code of the source superusers' choice. Partial dumps and partial restores do not limit that. If the source superusers are not trusted, the dumped SQL statements must be inspected before restoring. Non-plain-text dumps can be inspected by using pg\_restore's -f file option. Note that the client running the dump and restore need not trust the source or destination superusers.

## Options

The following command-line options control the content and format of the output.

*dbname*

Specifies the name of the database to be dumped. If this is not specified, the environment variable PGDATABASE is used. If that is not set, the user name specified for the connection is used.

**-a**  
**--data-only**

Dump only the data, not the schema (data definitions) or statistics. Table data, large objects, and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

**-b**  
**--large-objects**  
**--blobs** (deprecated)

Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, `--schema-only`, `--statistics-only`, or `--no-data` is specified. The `-b` switch is therefore only useful to add large objects to dumps where a specific schema or table has been requested. Note that large objects are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` or `--statistics-only` is.

**-B**  
**--no-large-objects**  
**--no-blobs** (deprecated)

Exclude large objects in the dump.

When both `-b` and `-B` are given, the behavior is to output large objects, when data is being dumped, see the `-b` documentation.

**-c**  
**--clean**

Output commands to **DROP** all the dumped database objects prior to outputting the commands for creating them. This option is useful when the restore is to overwrite an existing database. If any of the objects do not exist in the destination database, ignorable error messages will be reported during restore, unless `--if-exists` is also specified.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

**-C**  
**--create**

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also specified, the script drops and recreates the target database before reconnecting to it.

With `--create`, the output also includes the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also dumped, unless `--no-acl` is specified.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

**-e** *pattern*  
**--extension=pattern**

Dump only extensions matching *pattern*. When this option is not specified, all non-system extensions in the target database will be dumped. Multiple extensions can be selected by writing

multiple `-e` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see Patterns), so multiple extensions can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

Any configuration relation registered by `pg_extension_config_dump` is included in the dump if its extension is specified by `--extension`.

### Note

When `-e` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected extension(s) might depend upon. Therefore, there is no guarantee that the results of a specific-extension dump can be successfully restored by themselves into a clean database.

`-E encoding`  
`--encoding=encoding`

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.) The supported encodings are described in Section 23.3.1.

`-f file`  
`--file=file`

Send output to the specified file. This parameter can be omitted for file based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

`-F format`  
`--format=format`

Selects the format of the output. *format* can be one of the following:

`p`  
`plain`

Output a plain-text SQL script file (the default).

`c`  
`custom`

Output a custom-format archive suitable for input into `pg_restore`. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is also compressed by default.

`d`  
`directory`

Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and large object being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip`, `lz4`, or `zstd` tools. This format is compressed by default using `gzip` and also supports parallel dumps.

t  
tar

Output a **tar**-format archive suitable for input into `pg_restore`. The tar format is compatible with the directory format: extracting a tar-format archive produces a valid directory-format archive. However, the tar format does not support compression. Also, when using tar format the relative order of table data items cannot be changed during restore.

`-j njobs`  
`--jobs=njobs`

Run the dump in parallel by dumping *njobs* tables simultaneously. This option may reduce the time needed to perform the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

`pg_dump` will open *njobs* + 1 connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` leader process requests shared locks (ACCESS SHARE) on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the leader process to be released. Consequently any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so `pg_dump` has no choice but to abort the dump.

To perform a parallel dump, the database server needs to support synchronized snapshots, a feature that was introduced in PostgreSQL 9.2 for primary servers and 10 for standbys. With this feature, database clients can ensure they see the same data set even though they use different connections. `pg_dump -j` uses multiple database connections; it connects to the database once with the leader process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

`-n pattern`  
`--schema=pattern`

Dump only schemas matching *pattern*; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see Patterns), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples below.

### Note

When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

**Note**

Non-schema objects such as large objects are not dumped when `-n` is specified. You can add large objects back to the dump with the `--large-objects` switch.

`-N pattern`  
`--exclude-schema=pattern`

Do not dump any schemas matching *pattern*. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns.

When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-R`  
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`  
`--schema-only`

Dump only the object definitions (schema), not data or statistics.

This option cannot be used with `--data-only` or `--statistics-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

To exclude table data for only a subset of tables in the database, see `--exclude-table-data`.

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t pattern`  
`--table=pattern`

Dump only tables with names matching *pattern*. Multiple tables can be selected by writing multiple `-t` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql's \d` commands (see Patterns), so multiple tables can also be selected by writing

wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples below.

As well as tables, this option can be used to dump the definition of matching views, materialized views, foreign tables, and sequences. It will not dump the contents of views or materialized views, and the contents of foreign tables will only be dumped if the corresponding foreign server is specified with `--include-foreign-data`.

The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

### Note

When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

`-T pattern`  
`--exclude-table=pattern`

Do not dump any tables matching *pattern*. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns.

When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

`-v`  
`--verbose`

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

`-V`  
`--version`

Print the `pg_dump` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`-Z level`  
`-Z method[:detail]`  
`--compress=level`  
`--compress=method[:detail]`

Specify the compression method and/or the compression level to use. The compression method can be set to `gzip`, `lz4`, `zstd`, or `none` for no compression. A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form `keyword` or `keyword=value`. Currently, the supported keywords are `level` and `long`.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, `gzip` compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

For the custom and directory archive formats, this specifies compression of individual table-data segments, and the default is to compress using `gzip` at a moderate level. For plain text output, setting a nonzero compression level causes the entire output file to be compressed, as though it had been fed through `gzip`, `lz4`, or `zstd`; but the default is not to compress. With `zstd` compression, `long` mode may improve the compression ratio, at the cost of increased memory use.

The tar archive format currently does not support compression at all.

#### `--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

#### `--column-inserts`

#### `--attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

#### `--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

#### `--disable-triggers`

This option is relevant only when creating a dump that includes data but does not include schema. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is restored. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data restore.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

#### `--enable-row-security`

This option is relevant only when dumping the contents of a table which has row security. By default, `pg_dump` will set `row_security` to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_dump` to set `row_security` to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

Note that if you use this option currently, you probably also want the dump be in `INSERT` format, as the `COPY FROM` during restore does not support row security.

#### `--exclude-extension=pattern`

Do not dump any extensions matching *pattern*. The pattern is interpreted according to the same rules as for `-e`. `--exclude-extension` can be given more than once to exclude extensions matching any of several patterns.

When both `-e` and `--exclude-extension` are given, the behavior is to dump just the extensions that match at least one `-e` switch but no `--exclude-extension` switches. If `--exclude-extension` appears without `-e`, then extensions matching `--exclude-extension` are excluded from what is otherwise a normal dump.

**--exclude-table-and-children=*pattern***

This is the same as the `-T/--exclude-table` option, except that it also excludes any partitions or inheritance child tables of the table(s) matching the *pattern*.

**--exclude-table-data=*pattern***

Do not dump data for any tables matching *pattern*. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only` or `--statistics-only`.

**--exclude-table-data-and-children=*pattern***

This is the same as the `--exclude-table-data` option, except that it also excludes data of any partitions or inheritance child tables of the table(s) matching the *pattern*.

**--extra-float-digits=*ndigits***

Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

**--filter=*filename***

Specify a filename from which to read patterns for objects to include or exclude from the dump. The patterns are interpreted according to the same rules as the corresponding options: `-t/--table`, `--table-and-children`, `-T/--exclude-table`, and `--exclude-table-and-children` for tables, `-n/--schema` and `-N/--exclude-schema` for schemas, `--include-foreign-data` for data on foreign servers, `--exclude-table-data` and `--exclude-table-data-and-children` for table data, and `-e/--extension` and `--exclude-extension` for extensions. To read from STDIN, use `-` as the filename. The `--filter` option can be specified in conjunction with the above listed options for including or excluding objects, and can also be specified more than once for multiple filter files.

The file lists one object pattern per row, with the following format:

```
{ include | exclude } { extension | foreign_data | table |
table_and_children | table_data | table_data_and_children |
schema } PATTERN
```

The first keyword specifies whether the objects matched by the pattern are to be included or excluded. The second keyword specifies the type of object to be filtered using the pattern:

- **extension**: extensions. This works like the `-e/--extension` or `--exclude-extension` option.
- **foreign\_data**: data on foreign servers. This works like the `--include-foreign-data` option. This keyword can only be used with the `include` keyword.
- **table**: tables. This works like the `-t/--table` or `-T/--exclude-table` option.
- **table\_and\_children**: tables including any partitions or inheritance child tables. This works like the `--table-and-children` or `--exclude-table-and-children` option.
- **table\_data**: table data of any tables matching *pattern*. This works like the `--exclude-table-data` option. This keyword can only be used with the `exclude` keyword.

- **table\_data\_and\_children**: table data of any tables matching *pattern* as well as any partitions or inheritance children of the table(s). This works like the `--exclude-table-data-and-children` option. This keyword can only be used with the `exclude` keyword.
- **schema**: schemas. This works like the `-n/--schema` or `-N/--exclude-schema` option.

Lines starting with `#` are considered comments and ignored. Comments can be placed after an object pattern row as well. Blank lines are also ignored. See Patterns for how to perform quoting in patterns.

Example files are listed below in the Examples section.

#### `--if-exists`

Use `DROP ... IF EXISTS` commands to drop objects in `--clean` mode. This suppresses “does not exist” errors that might otherwise be reported. This option is not valid unless `--clean` is also specified.

#### `--include-foreign-data=foreignserver`

Dump the data for any foreign table with a foreign server matching *foreignserver* pattern. Multiple foreign servers can be selected by writing multiple `--include-foreign-data` switches. Also, the *foreignserver* parameter is interpreted as a pattern according to the same rules used by `psql's \d` commands (see Patterns), so multiple foreign servers can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples below. The only exception is that an empty pattern is disallowed.

#### Note

Using wildcards in `--include-foreign-data` may result in access to unexpected foreign servers. Also, to use this option securely, make sure that the named server must have a trusted owner.

#### Note

When `--include-foreign-data` is specified, `pg_dump` does not check that the foreign table is writable. Therefore, there is no guarantee that the results of a foreign table dump can be successfully restored.

#### `--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

#### `--load-via-partition-root`

When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when restoring data on a server where rows do not always fall into the same partitions as they did on

the original server. That could happen, for example, if the partitioning column is of type text and the two systems have different definitions of the collation used to sort the partitioning column.

**--lock-wait-timeout=*timeout***

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by SET `statement_timeout`. (Allowed formats vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions.)

**--no-comments**

Do not dump COMMENT commands.

**--no-data**

Do not dump data.

**--no-policies**

Do not dump row security policies.

**--no-publications**

Do not dump publications.

**--no-schema**

Do not dump schema (data definitions).

**--no-security-labels**

Do not dump security labels.

**--no-statistics**

Do not dump statistics. This is the default.

**--no-subscriptions**

Do not dump subscriptions.

**--no-sync**

By default, `pg_dump` will wait for all files to be written safely to disk. This option causes `pg_dump` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

**--no-table-access-method**

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

**--no-tablespaces**

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

**--no-toast-compression**

Do not output commands to set TOAST compression methods. With this option, all columns will be restored with the default compression setting.

**--no-unlogged-table-data**

Do not dump the contents of unlogged tables and sequences. This option has no effect on whether or not the table and sequence definitions (schema) are dumped; it only suppresses dumping the table and sequence data. Data in unlogged tables and sequences is always excluded when dumping from a standby server.

**--on-conflict-do-nothing**

Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts`, `--column-inserts` or `--rows-per-insert` is also specified.

**--quote-all-identifiers**

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

**--restrict-key=*restrict\_key***

Use the provided string as the `psql \restrict` key in the dump output. This can only be specified for plain-text dumps, i.e., when `--format` is set to `plain` or the `--format` option is omitted. If no restrict key is specified, `pg_dump` will generate a random one as needed. Keys may contain only alphanumeric characters.

This option is primarily intended for testing purposes and other scenarios that require repeatable output (e.g., comparing dump files). It is not recommended for general use, as a malicious server with advance knowledge of the key may be able to inject arbitrary code that will be executed on the machine that runs `psql` with the dump output.

**--rows-per-insert=*nrows***

Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

**--section=*sectionname***

Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The data section contains actual table data, large-object contents, sequence values, and statistics for tables, materialized views, and foreign tables. Post-data items include definitions of indexes, triggers, rules, statistics for indexes, and constraints other than validated check and not-null constraints. Pre-data items include all other data definition items.

**--sequence-data**

Include sequence data in the dump. This is the default behavior except when `--no-data`, `--schema-only`, or `--statistics-only` is specified.

**--serializable-deferrable**

Use a `serializable` transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a `serialization_failure`. See Chapter 13 for more information about transaction isolation and concurrency control.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

**--snapshot=snapshotname**

Use the specified synchronized snapshot when making a dump of the database (see Table 9.100 for more details).

This option is useful when needing to synchronize the dump with a logical replication slot (see Chapter 47) or with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

**--statistics**

Dump optimizer statistics.

**--statistics-only**

Dump only the statistics, not the schema (data definitions) or data. Optimizer statistics for tables, materialized views, foreign tables, and indexes are dumped.

**--strict-names**

Require that each extension (`-e/--extension`), schema (`-n/--schema`) and table (`-t/--table`) pattern match at least one extension/schema/table in the database to be dumped. This also applies to filters used with `--filter`. Note that if none of the extension/schema/table patterns find matches, `pg_dump` will generate an error even without `--strict-names`.

This option has no effect on `--exclude-extension`, `-N/--exclude-schema`, `-T/--exclude-table`, or `--exclude-table-data`. An exclude pattern failing to match any objects is not considered an error.

**--sync-method=method**

When set to `fsync`, which is the default, `pg_dump --format=directory` will recursively open and synchronize all files in the archive directory.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file system that contains the archive directory. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used or `--format` is not set to `directory`.

**--table-and-children=*pattern***

This is the same as the **-t/-table** option, except that it also includes any partitions or inheritance child tables of the table(s) matching the *pattern*.

**--use-set-session-authorization**

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using SET SESSION AUTHORIZATION will certainly require superuser privileges to restore correctly, whereas ALTER OWNER requires lesser privileges.

**-?**

**--help**

Show help about pg\_dump command line arguments, and exit.

The following command-line options control the database connection parameters.

**-d *dbname***

**--dbname=*dbname***

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

**-h *host***

**--host=*host***

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

**-p *port***

**--port=*port***

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

**-U *username***

**--username=*username***

User name to connect as.

**-w**

**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**

**--password**

Force pg\_dump to prompt for a password before connecting to a database.

This option is never essential, since pg\_dump will automatically prompt for a password if the server demands password authentication. However, pg\_dump will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing **-W** to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dump` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dump`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Environment

PGDATABASE  
PGHOST  
PGOPTIONS  
PGPORT  
PGUSER

Default connection parameters.

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 32.15).

## Diagnostics

`pg_dump` internally executes `SELECT` statements. If you have problems running `pg_dump`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

The database activity of `pg_dump` is normally collected by the cumulative statistics system. If this is undesirable, you can set parameter `track_counts` to false via `PGOPTIONS` or the `ALTER USER` command.

## Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of `pg_dump` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When a dump without schema is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to disable triggers on user tables before inserting the data, and then commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

When `--statistics` is specified, `pg_dump` will include most optimizer statistics in the resulting dump file. This does not include all statistics, such as those created explicitly with `CREATE STATISTICS`, custom statistics added by an extension, or statistics collected by the cumulative statistics system. Therefore, it may still be useful to run `ANALYZE` after restoring from a dump file to ensure optimal performance; see Section 24.1.3 and Section 24.1.6 for more information.

Because `pg_dump` is used to transfer data to newer versions of PostgreSQL, the output of `pg_dump` can be expected to load into PostgreSQL server versions newer than `pg_dump`'s version. `pg_dump` can

also dump from PostgreSQL servers older than its own version. (Currently, servers back to version 9.2 are supported.) However, `pg_dump` cannot dump from PostgreSQL servers newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`'s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different PostgreSQL versions.

When dumping logical replication subscriptions, `pg_dump` will generate `CREATE SUBSCRIPTION` commands that use the `connect = false` option, so that restoring the subscription does not make remote connections for creating a replication slot or for initial table copy. That way, the dump can be restored without requiring network access to the remote servers. It is then up to the user to reactivate the subscriptions in a suitable way. If the involved hosts have changed, the connection information might have to be changed. It might also be appropriate to truncate the target tables before initiating a new full table copy. If users intend to copy initial data during refresh they must create the slot with `two_phase = false`. After the initial sync, the `two_phase` option will be automatically enabled by the subscriber if the subscription had been originally created with `two_phase = true` option.

It is generally recommended to use the `-X (--no-psqlrc)` option when restoring a database from a plain-text `pg_dump` script to ensure a clean restore process and prevent potential conflicts with non-default `psql` configurations.

## Examples

To dump a database called `mydb` into an SQL-script file:

```
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
$ psql -X -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```
$ pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
$ pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
$ pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```
$ pg_restore -d newdb db.dump
```

To reload an archive file into the same database it was dumped from, discarding the current contents of that database:

```
$ pg_restore -d postgres --clean --create db.dump
```

To dump a single table named `mytab`:

```
$ pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with `emp` in the `detroit` schema, except for the table named `employee_log`:

```
$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```

To dump all schemas whose names start with `east` or `west` and end in `gsm`, excluding any schemas whose names contain the word `test`:

```
$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same, using regular expression notation to consolidate the switches:

```
$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with `ts_`:

```
$ pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case (see [Patterns](#)). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

```
$ pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql
```

To dump all tables whose names start with `mytable`, except for table `mytable2`, specify a filter file `filter.txt` like:

```
include table mytable*
exclude table mytable2
```

```
$ pg_dump --filter=filter.txt mydb > db.sql
```

# pg\_dumpall

pg\_dumpall — extract a PostgreSQL database cluster into a script file

## Synopsis

pg\_dumpall [*connection-option...*] [*option...*]

## Description

pg\_dumpall is a utility for writing out (“dumping”) all PostgreSQL databases of a cluster into one script file. The script file contains SQL commands that can be used as input to psql to restore the databases. It does this by calling pg\_dump for each database in the cluster. pg\_dumpall also dumps global objects that are common to all databases, namely database roles, tablespaces, and privilege grants for configuration parameters. (pg\_dump does not save these objects.)

Since pg\_dumpall reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add roles and create databases.

The SQL script will be written to the standard output. Use the `-f/-file` option or shell operators to redirect it into a file.

pg\_dumpall needs to connect several times to the PostgreSQL server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See Section 32.16 for more information.

### Warning

Restoring a dump causes the destination to execute arbitrary code of the source superusers' choice. Partial dumps and partial restores do not limit that. If the source superusers are not trusted, the dumped SQL statements must be inspected before restoring. Note that the client running the dump and restore need not trust the source or destination superusers.

## Options

The following command-line options control the content and format of the output.

`-a`  
`--data-only`

Dump only the data, not the schema (data definitions) or statistics.

`-c`  
`--clean`

Emit SQL commands to **DROP** all the dumped databases, roles, and tablespaces before recreating them. This option is useful when the restore is to overwrite an existing cluster. If any of the objects do not exist in the destination cluster, ignorable error messages will be reported during restore, unless `--if-exists` is also specified.

`-E encoding`  
`--encoding=encoding`

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

`-f filename`  
`--file=filename`

Send output to the specified file. If this is omitted, the standard output is used.

`-g`  
`--globals-only`

Dump only global objects (roles and tablespaces), no databases.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dumpall` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

`-r`  
`--roles-only`

Dump only roles, no databases or tablespaces.

`-s`  
`--schema-only`

Dump only the object definitions (schema), not data.

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t`  
`--tablespaces-only`

Dump only tablespaces, no databases or roles.

`-v`  
`--verbose`

Specifies verbose mode. This will cause `pg_dumpall` to output start/stop times to the dump file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error. The option is also passed down to `pg_dump`.

`-V`  
`--version`

Print the `pg_dumpall` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

--column-inserts  
--attribute-inserts

Dump data as INSERT commands with explicit column names (INSERT INTO *table* (*column*, ...) VALUES ...). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases.

--disable-dollar-quoting

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers

This option is relevant only when creating a dump with data and without schema. It instructs pg\_dumpall to include commands to temporarily disable triggers on the target tables while the data is restored. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data restore.

Presently, the commands emitted for --disable-triggers must be done as superuser. So, you should also specify a superuser name with -S, or preferably be careful to start the resulting script as a superuser.

--exclude-database=*pattern*

Do not dump databases whose name matches *pattern*. Multiple patterns can be excluded by writing multiple --exclude-database switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by psql's \d commands (see Patterns), so multiple databases can also be excluded by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent shell wildcard expansion.

--extra-float-digits=*ndigits*

Use the specified value of extra\_float\_digits when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

--filter=*filename*

Specify a filename from which to read patterns for databases excluded from the dump. The patterns are interpreted according to the same rules as --exclude-database. To read from STDIN, use - as the filename. The --filter option can be specified in conjunction with --exclude-database for excluding databases, and can also be specified more than once for multiple filter files.

The file lists one database pattern per row, with the following format:

```
exclude database PATTERN
```

Lines starting with # are considered comments and ignored. Comments can be placed after an object pattern row as well. Blank lines are also ignored. See Patterns for how to perform quoting in patterns.

--if-exists

Use DROP ... IF EXISTS commands to drop objects in --clean mode. This suppresses “does not exist” errors that might otherwise be reported. This option is not valid unless --clean is also specified.

**--inserts**

Dump data as **INSERT** commands (rather than **COPY**). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Note that the restore might fail altogether if you have rearranged column order. The **--column-inserts** option is safer, though even slower.

**--load-via-partition-root**

When dumping data for a table partition, make the **COPY** or **INSERT** statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when restoring data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type text and the two systems have different definitions of the collation used to sort the partitioning column.

**--lock-wait-timeout=timeout**

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by **SET statement\_timeout**.

**--no-comments**

Do not dump **COMMENT** commands.

**--no-data**

Do not dump data.

**--no-policies**

Do not dump row security policies.

**--no-publications**

Do not dump publications.

**--no-role-passwords**

Do not dump passwords for roles. When restored, roles will have a null password, and password authentication will always fail until the password is set. Since password values aren't needed when this option is specified, the role information is read from the catalog view **pg\_roles** instead of **pg\_authid**. Therefore, this option also helps if access to **pg\_authid** is restricted by some security policy.

**--no-schema**

Do not dump schema (data definitions).

**--no-security-labels**

Do not dump security labels.

**--no-statistics**

Do not dump statistics. This is the default.

**--no-subscriptions**

Do not dump subscriptions.

**--no-sync**

By default, `pg_dumpall` will wait for all files to be written safely to disk. This option causes `pg_dumpall` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

**--no-table-access-method**

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

**--no-tablespaces**

Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

**--no-toast-compression**

Do not output commands to set TOAST compression methods. With this option, all columns will be restored with the default compression setting.

**--no-unlogged-table-data**

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

**--on-conflict-do-nothing**

Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts` or `--column-inserts` is also specified.

**--quote-all-identifiers**

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

**--restrict-key=*restrict\_key***

Use the provided string as the `psql \restrict` key in the dump output. If no restrict key is specified, `pg_dumpall` will generate a random one as needed. Keys may contain only alphanumeric characters.

This option is primarily intended for testing purposes and other scenarios that require repeatable output (e.g., comparing dump files). It is not recommended for general use, as a malicious server with advance knowledge of the key may be able to inject arbitrary code that will be executed on the machine that runs `psql` with the dump output.

**--rows-per-insert=*nrows***

Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

**--statistics**

Dump optimizer statistics.

**--statistics-only**

Dump only the statistics, not the schema (data definitions) or data. Optimizer statistics for tables, materialized views, foreign tables, and indexes are dumped.

**--sequence-data**

Include sequence data in the dump. This is the default behavior except when **--no-data**, **--schema-only**, or **--statistics-only** is specified.

**--use-set-session-authorization**

Output SQL-standard **SET SESSION AUTHORIZATION** commands instead of **ALTER OWNER** commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

**-?****--help**

Show help about pg\_dumpall command line arguments, and exit.

The following command-line options control the database connection parameters.

**-d *connstr*****--dbname=*connstr***

Specifies parameters used to connect to the server, as a connection string; these will override any conflicting command line options.

The option is called **--dbname** for consistency with other client applications, but because pg\_dumpall needs to connect to many databases, the database name in the connection string will be ignored. Use the **-l** option to specify the name of the database used for the initial connection, which will dump global objects and discover what other databases should be dumped.

**-h *host*****--host=*host***

Specifies the host name of the machine on which the database server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the **PGHOST** environment variable, if set, else a Unix domain socket connection is attempted.

**-l *dbname*****--database=*dbname***

Specifies the name of the database to connect to for dumping global objects and discovering what other databases should be dumped. If not specified, the **postgres** database will be used, and if that does not exist, **template1** will be used.

**-p *port*****--port=*port***

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the **PGPORT** environment variable, if set, or a compiled-in default.

**-U *username*****--username=*username***

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_dumpall` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dumpall` will automatically prompt for a password if the server demands password authentication. However, `pg_dumpall` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it's better to set up a `~/ .pgpass` file than to rely on manual password entry.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dumpall` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dumpall`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Environment

`PGHOST`  
`PGOPTIONS`  
`PGPORT`  
`PGUSER`

Default connection parameters

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 32.15).

## Notes

Since `pg_dumpall` calls `pg_dump` internally, some diagnostic messages will refer to `pg_dump`.

The `--clean` option can be useful even when your intention is to restore the dump script into a fresh cluster. Use of `-c` `clean` authorizes the script to drop and re-create the built-in `postgres` and `template1` databases, ensuring that those databases will retain the same properties (for instance, locale and encoding) that they had in the source cluster. Without the option, those databases will retain their existing database-level properties, as well as any pre-existing contents.

When `--statistics` is specified, `pg_dumpall` will include most optimizer statistics in the resulting dump file. This does not include all statistics, such as those created explicitly with `CREATE STATISTICS`, custom statistics added by an extension, or statistics collected by the cumulative statistics system. Therefore, it may still be useful to run `ANALYZE` on each database after restoring from

a dump file to ensure optimal performance. You can also run `vacuumdb -a -z` to analyze all databases.

The dump script should not be expected to run completely without errors. In particular, because the script will issue `CREATE ROLE` for every role existing in the source cluster, it is certain to get a “role already exists” error for the bootstrap superuser, unless the destination cluster was initialized with a different bootstrap superuser name. This error is harmless and should be ignored. Use of the `--clean` option is likely to produce additional harmless error messages about non-existent objects, although you can minimize those by adding `--if-exists`.

`pg_dumpall` requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

It is generally recommended to use the `-X (--no-psqlrc)` option when restoring a database from a `pg_dumpall` script to ensure a clean restore process and prevent potential conflicts with non-default `psql` configurations. Additionally, because the `pg_dumpall` script may include `psql` meta-commands, it may be incompatible with clients other than `psql`.

## Examples

To dump all databases:

```
$ pg_dumpall > db.out
```

To restore database(s) from this file, you can use:

```
$ psql -X -f db.out -d postgres
```

It is not important which database you connect to here since the script file created by `pg_dumpall` will contain the appropriate commands to create and connect to the saved databases. An exception is that if you specified `--clean`, you must connect to the `postgres` database initially; the script will attempt to drop other databases immediately, and that will fail for the database you are connected to.

## See Also

Check `pg_dump` for details on possible error conditions.

---

# pg\_isready

pg\_isready — check the connection status of a PostgreSQL server

## Synopsis

pg\_isready [*connection-option...*] [*option...*]

## Description

pg\_isready is a utility for checking the connection status of a PostgreSQL database server. The exit status specifies the result of the connection check.

## Options

-d *dbname*  
--dbname=*dbname*

Specifies the name of the database to connect to. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

-h *hostname*  
--host=*hostname*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

-q  
--quiet

Do not display status message. This is useful when scripting.

-t *seconds*  
--timeout=*seconds*

The maximum number of seconds to wait when attempting connection before returning that the server is not responding. Setting to 0 disables. The default is 3 seconds.

-U *username*  
--username=*username*

Connect to the database as the user *username* instead of the default.

-V  
--version

Print the pg\_isready version and exit.

-?  
--help

Show help about pg\_isready command line arguments, and exit.

## Exit Status

`pg_isready` returns `0` to the shell if the server is accepting connections normally, `1` if the server is rejecting connections (for example during startup), `2` if there was no response to the connection attempt, and `3` if no attempt was made (for example due to invalid parameters).

## Environment

`pg_isready`, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

It is not necessary to supply correct user name, password, or database name values to obtain the server status; however, if incorrect values are provided, the server will log a failed connection attempt.

## Examples

Standard Usage:

```
$ pg_isready
/tmp:5432 - accepting connections
$ echo $?
0
```

Running with connection parameters to a PostgreSQL cluster in startup:

```
$ pg_isready -h localhost -p 5433
localhost:5433 - rejecting connections
$ echo $?
1
```

Running with connection parameters to a non-responsive PostgreSQL cluster:

```
$ pg_isready -h someremotehost
someremotehost:5432 - no response
$ echo $?
2
```

---

# pg\_receivewal

pg\_receivewal — stream write-ahead logs from a PostgreSQL server

## Synopsis

pg\_receivewal [*option...*]

## Description

pg\_receivewal is used to stream the write-ahead log from a running PostgreSQL cluster. The write-ahead log is streamed using the streaming replication protocol, and is written to a local directory of files. This directory can be used as the archive location for doing a restore using point-in-time recovery (see Section 25.3).

pg\_receivewal streams the write-ahead log in real time as it's being generated on the server, and does not wait for segments to complete like `archive_command` and `archive_library` do. For this reason, it is not necessary to set `archive_timeout` when using pg\_receivewal.

Unlike the WAL receiver of a PostgreSQL standby server, pg\_receivewal by default flushes WAL data only when a WAL file is closed. The option `--synchronous` must be specified to flush WAL data in real time. Since pg\_receivewal does not apply WAL, you should not allow it to become a synchronous standby when `synchronous_commit` equals `remote_apply`. If it does, it will appear to be a standby that never catches up, and will cause transaction commits to block. To avoid this, you should either configure an appropriate value for `synchronous_standby_names`, or specify `application_name` for pg\_receivewal that does not match it, or change the value of `synchronous_commit` to something other than `remote_apply`.

The write-ahead log is streamed over a regular PostgreSQL connection and uses the replication protocol. The connection must be made with a user having `REPLICATION` permissions (see Section 21.2) or a superuser, and `pg_hba.conf` must permit the replication connection. The server must also be configured with `max_wal_senders` set high enough to leave at least one session available for the stream.

The starting point of the write-ahead log streaming is calculated when pg\_receivewal starts:

1. First, scan the directory where the WAL segment files are written and find the newest completed segment file, using as the starting point the beginning of the next WAL segment file.
2. If a starting point cannot be calculated with the previous method, and if a replication slot is used, an extra `READ_REPLICATION_SLOT` command is issued to retrieve the slot's `restart_lsn` to use as the starting point. This option is only available when streaming write-ahead logs from PostgreSQL 15 and up.
3. If a starting point cannot be calculated with the previous method, the latest WAL flush location is used as reported by the server from an `IDENTIFY_SYSTEM` command.

If the connection is lost, or if it cannot be initially established, with a non-fatal error, pg\_receivewal will retry the connection indefinitely, and reestablish streaming as soon as possible. To avoid this behavior, use the `-n` parameter.

In the absence of fatal errors, pg\_receivewal will run until terminated by the SIGINT (**Control+C**) or SIGTERM signal.

## Options

`-D directory`  
`--directory=directory`

Directory to write the output to.

This parameter is required.

**-E *lsn***  
**--endpos=*lsn***

Automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN.

If there is a record with LSN exactly equal to *lsn*, the record will be processed.

**--if-not-exists**

Do not error out when **--create-slot** is specified and a slot with the specified name already exists.

**-n**  
**--no-loop**

Don't loop on connection errors. Instead, exit right away with an error.

**--no-sync**

This option causes `pg_receivewal` to not force WAL data to be flushed to disk. This is faster, but means that a subsequent operating system crash can leave the WAL segments corrupt. Generally, this option is useful for testing but should not be used when doing WAL archiving on a production deployment.

This option is incompatible with **--synchronous**.

**-s *interval***  
**--status-interval=*interval***

Specifies the number of seconds between status packets sent back to the server. This allows for easier monitoring of the progress from server. A value of zero disables the periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout disconnect. The default value is 10 seconds.

**-S *slotname***  
**--slot=*slotname***

Require `pg_receivewal` to use an existing replication slot (see Section 26.2.6). When this option is used, `pg_receivewal` will report a flush position to the server, indicating when each segment has been synchronized to disk so that the server can remove that segment if it is not otherwise needed.

When the replication client of `pg_receivewal` is configured on the server as a synchronous standby, then using a replication slot will report the flush position to the server, but only when a WAL file is closed. Therefore, that configuration will cause transactions on the primary to wait for a long time and effectively not work satisfactorily. The option **--synchronous** (see below) must be specified in addition to make this work correctly.

**--synchronous**

Flush the WAL data to disk immediately after it has been received. Also send a status packet back to the server immediately after flushing, regardless of **--status-interval**.

This option should be specified if the replication client of `pg_receivewal` is configured on the server as a synchronous standby, to ensure that timely feedback is sent to the server.

**-v**  
**--verbose**

Enables verbose mode.

```
-Z level
-Z method[:detail]
--compress=level
--compress=method[:detail]
```

Enables compression of write-ahead logs.

The compression method can be set to `gzip`, `lz4` (if PostgreSQL was compiled with `--with-lz4`) or `none` for no compression. A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form *keyword* or *keyword=value*. Currently, the only supported keyword is `level`.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, `gzip` compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

The suffix `.gz` will automatically be added to all filenames when using `gzip`, and the suffix `.lz4` is added when using `lz4`.

The following command-line options control the database connection parameters.

```
-d connstr
--dbname=connstr
```

Specifies parameters used to connect to the server, as a connection string; these will override any conflicting command line options.

This option is called `--dbname` for consistency with other client applications, but because `pg_receivewal` doesn't connect to any particular database in the cluster, any database name included in the connection string will be ignored by the server. However, a database name supplied that way overrides the default database name (`replication`) for purposes of looking up the replication connection's password in `~/ .pgpass`. Similarly, middleware or proxies used in connecting to PostgreSQL might utilize the name for purposes such as connection routing.

```
-h host
--host=host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

```
-p port
--port=port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_receivewal` to prompt for a password before connecting to a database.

This option is never essential, since `pg_receivewal` will automatically prompt for a password if the server demands password authentication. However, `pg_receivewal` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`pg_receivewal` can perform one of the two following actions in order to control physical replication slots:

`--create-slot`

Create a new physical replication slot with the name specified in `--slot`, then exit.

`--drop-slot`

Drop the replication slot with the name specified in `--slot`, then exit.

Other options are also available:

`-V`  
`--version`

Print the `pg_receivewal` version and exit.

`-?`  
`--help`

Show help about `pg_receivewal` command line arguments, and exit.

## Exit Status

`pg_receivewal` will exit with status 0 when terminated by the `SIGINT` or `SIGTERM` signal. (That is the normal way to end it. Hence it is not an error.) For fatal errors or other signals, the exit status will be nonzero.

## Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by `libpq` (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

When using `pg_receivewal` instead of `archive_command` or `archive_library` as the main WAL backup method, it is strongly recommended to use replication slots. Otherwise, the server is free to recycle or remove write-ahead log files before they are backed up, because it does not have any information, either from `archive_command` or `archive_library` or the replication slots, about how far the WAL stream has been archived. Note, however, that a replication slot will fill up the server's disk space if the receiver does not keep up with fetching the WAL data.

`pg_receivewal` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

## Examples

To stream the write-ahead log from the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/archive`:

```
$ pg_receivewal -h mydbserver -D /usr/local/pgsql/archive
```

# pg\_recvlogical

pg\_recvlogical — control PostgreSQL logical decoding streams

## Synopsis

`pg_recvlogical [option...]`

## Description

`pg_recvlogical` controls logical decoding replication slots and streams data from such replication slots.

It creates a replication-mode connection, so it is subject to the same constraints as `pg_receivewal`, plus those for logical replication (see Chapter 47).

`pg_recvlogical` has no equivalent to the logical decoding SQL interface's peek and get modes. It sends replay confirmations for data lazily as it receives it and on clean exit. To examine pending data on a slot without consuming it, use `pg_logical_slot_peek_changes`.

In the absence of fatal errors, `pg_recvlogical` will run until terminated by the SIGINT (**Control+C**) or SIGTERM signal.

When `pg_recvlogical` receives a SIGHUP signal, it closes the current output file and opens a new one using the filename specified by the `--file` option. This allows us to rotate the output file by first renaming the current file and then sending a SIGHUP signal to `pg_recvlogical`.

## Options

At least one of the following options must be specified to select an action:

### `--create-slot`

Create a new logical replication slot with the name specified by `--slot`, using the output plugin specified by `--plugin`, for the database specified by `--dbname`.

The `--slot` and `--dbname` are required for this action.

The `--enable-two-phase` and `--enable-failover` options can be specified with `--create-slot`.

### `--drop-slot`

Drop the replication slot with the name specified by `--slot`, then exit.

The `--slot` is required for this action.

### `--start`

Begin streaming changes from the logical replication slot specified by `--slot`, continuing until terminated by a signal. If the server side change stream ends with a server shutdown or disconnect, retry in a loop unless `--no-loop` is specified.

The `--slot` and `--dbname`, `--file` are required for this action.

The stream format is determined by the output plugin specified when the slot was created.

The connection must be to the same database used to create the slot.

`--create-slot` and `--start` can be specified together. `--drop-slot` cannot be combined with another action.

The following command-line options control the location and format of the output and other replication behavior:

`-E lsn`  
`--endpos=lsn`

In `--start` mode, automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN. If specified when not in `--start` mode, an error is raised.

If there's a record with LSN exactly equal to `lsn`, the record will be output.

The `--endpos` option is not aware of transaction boundaries and may truncate output partway through a transaction. Any partially output transaction will not be consumed and will be replayed again when the slot is next read from. Individual messages are never truncated.

`--enable-failover`

Enables the slot to be synchronized to the standbys. This option may only be specified with `--create-slot`.

`-f filename`  
`--file=filename`

Write received and decoded transaction data into this file. Use `-` for stdout.

This parameter is required for `--start`.

`-F interval_seconds`  
`--fsync-interval=interval_seconds`

Specifies how often `pg_recvlogical` should issue `fsync()` calls to ensure the output file is safely flushed to disk.

The server will occasionally request the client to perform a flush and report the flush position to the server. This setting is in addition to that, to perform flushes more frequently.

Specifying an interval of 0 disables issuing `fsync()` calls altogether, while still reporting progress to the server. In this case, data could be lost in the event of a crash.

`-I lsn`  
`--startpos=lsn`

In `--start` mode, start replication from the given LSN. For details on the effect of this, see the documentation in Chapter 47 and Section 54.4. Ignored in other modes.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`  
`--no-loop`

When the connection to the server is lost, do not retry in a loop, just exit.

`-o name[=value]`  
`--option=name[=value]`

Pass the option *name* to the output plugin with, if specified, the option value *value*. Which options exist and their effects depends on the used output plugin.

**-P *plugin***  
**--plugin=*plugin***

When creating a slot, use the specified logical decoding output plugin. See Chapter 47. This option has no effect if the slot already exists.

**-s *interval\_seconds***  
**--status-interval=*interval\_seconds***

This option has the same effect as the option of the same name in `pg_receivewal`. See the description there.

**-S *slot\_name***  
**--slot=*slot\_name***

In `--start` mode, use the existing logical replication slot named *slot\_name*. In `--create-slot` mode, create the slot with this name. In `--drop-slot` mode, delete the slot with this name.

This parameter is required for any of actions.

**-t**  
**--enable-two-phase**  
**--two-phase** (deprecated)

Enables decoding of prepared transactions. This option may only be specified with `--create-slot`.

**-v**  
**--verbose**

Enables verbose mode.

The following command-line options control the database connection parameters.

**-d *dbname***  
**--dbname=*dbname***

The database to connect to. See the description of the actions for what this means in detail. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

This parameter is required for `--create-slot` and `--start`.

**-h *hostname-or-ip***  
**--host=*hostname-or-ip***

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

**-p *port***  
**--port=*port***

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

**-U *user***  
**--username=*user***

User name to connect as. Defaults to current operating system user name.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_recvlogical` to prompt for a password before connecting to a database.

This option is never essential, since `pg_recvlogical` will automatically prompt for a password if the server demands password authentication. However, `pg_recvlogical` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

The following additional options are available:

`-V`  
`--version`

Print the `pg_recvlogical` version and exit.

`-?`  
`--help`

Show help about `pg_recvlogical` command line arguments, and exit.

## Exit Status

`pg_recvlogical` will exit with status 0 when terminated by the `SIGINT` or `SIGTERM` signal. (That is the normal way to end it. Hence it is not an error.) For fatal errors or other signals, the exit status will be nonzero.

## Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by `libpq` (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

`pg_recvlogical` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

## Examples

See Section 47.1 for an example.

# pg\_restore

pg\_restore — restore a PostgreSQL database from an archive file created by pg\_dump

## Synopsis

pg\_restore [*connection-option...*] [*option...*] [*filename*]

## Description

pg\_restore is a utility for restoring a PostgreSQL database from an archive created by pg\_dump in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow pg\_restore to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

pg\_restore can operate in two modes. If a database name is specified, pg\_restore connects to that database and restores archive contents directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. This script output is equivalent to the plain text output format of pg\_dump. Some of the options controlling the output are therefore analogous to pg\_dump options.

Obviously, pg\_restore cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as INSERT commands” option, pg\_restore will not be able to load the data using COPY statements.

### Warning

Restoring a dump causes the destination to execute arbitrary code of the source superusers' choice. Partial dumps and partial restores do not limit that. If the source superusers are not trusted, the dumped SQL statements must be inspected before restoring. Non-plain-text dumps can be inspected by using pg\_restore's `-f file` option. Note that the client running the dump and restore need not trust the source or destination superusers.

## Options

pg\_restore accepts the following command line arguments.

*filename*

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

`-a`

`--data-only`

Restore only the data, not the schema (data definitions) or statistics. Table data, large objects, and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-c`

`--clean`

Before restoring database objects, issue commands to DROP all the objects that will be restored. This option is useful for overwriting an existing database. If any of the objects do not exist in the

destination database, ignorable error messages will be reported, unless `--if-exists` is also specified.

`-C`  
`--create`

Create the database before restoring into it. If `--clean` is also specified, drop and recreate the target database before connecting to it.

With `--create`, `pg_restore` also restores the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also restored, unless `--no-acl` is specified.

When this option is used, the database named with `-d` is used only to issue the initial `DROP DATABASE` and `CREATE DATABASE` commands. All data is restored into the database name that appears in the archive.

`-d dbname`  
`--dbname=dbname`

Connect to database *dbname* and restore directly into the database. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

`-e`  
`--exit-on-error`

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

`-f filename`  
`--file=filename`

Specify output file for generated script, or for the listing when used with `-l`. Use `-` for stdout.

`-F format`  
`--format=format`

Specify format of the archive. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. If specified, it can be one of the following:

`c`  
`custom`

The archive is in the custom format of `pg_dump`.

`d`  
`directory`

The archive is a directory archive.

`t`  
`tar`

The archive is a `tar` archive.

`-I index`  
`--index=index`

Restore definition of named index only. Multiple indexes may be specified with multiple `-I` switches.

**-j** *number-of-jobs*  
**--jobs=***number-of-jobs*

Run the most time-consuming steps of `pg_restore` — those that load data, create indexes, or create constraints — concurrently, using up to *number-of-jobs* concurrent sessions. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine. This option is ignored when emitting a script rather than connecting directly to a database server.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom and directory archive formats are supported with this option. The input must be a regular file or directory (not, for example, a pipe or standard input). Also, multiple jobs cannot be used together with the option `--single-transaction`.

**-l**  
**--list**

List the table of contents of the archive. The output of this operation can be used as input to the `-L` option. Note that if filtering switches such as `-n` or `-t` are used with `-l`, they will restrict the items listed.

**-L** *list-file*  
**--use-list=***list-file*

Restore only those archive elements that are listed in *list-file*, and restore them in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they will further restrict the items restored.

*list-file* is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

**-n** *schema*  
**--schema=***schema*

Restore only objects that are in the named schema. Multiple schemas may be specified with multiple `-n` switches. This can be combined with the `-t` option to restore just a specific table.

**-N** *schema*  
**--exclude-schema=***schema*

Do not restore objects that are in the named schema. Multiple schemas to be excluded may be specified with multiple `-N` switches.

When both `-n` and `-N` are given for the same schema name, the `-N` switch wins and the schema is excluded.

**-O**  
**--no-owner**

Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set

ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

`-P function-name(argtype [, ...])`  
`--function=function-name(argtype [, ...])`

Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents. Multiple functions may be specified with multiple `-P` switches.

`-R`  
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`  
`--schema-only`

Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option cannot be used with `--data-only` or `--statistics-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data --no-statistics`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used.

`-t table`  
`--table=table`

Restore definition and/or data of only the named table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple `-t` switches. This option can be combined with the `-n` option to specify table(s) in a particular schema.

### Note

When `-t` is specified, `pg_restore` makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed.

### Note

This flag does not behave identically to the `-t` flag of `pg_dump`. There is not currently any provision for wild-card matching in `pg_restore`, nor can you include a schema name within its `-t`. And, while `pg_dump`'s `-t` flag will also dump subsidiary objects (such as indexes) of the selected table(s), `pg_restore`'s `-t` flag does not include such subsidiary objects.

**Note**

In versions prior to PostgreSQL 9.6, this flag matched only tables, not any other type of relation.

**-T trigger**  
**--trigger=trigger**

Restore named trigger only. Multiple triggers may be specified with multiple **-T** switches.

**-v**  
**--verbose**

Specifies verbose mode. This will cause `pg_restore` to output detailed object comments and start/stop times to the output file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

**-V**  
**--version**

Print the `pg_restore` version and exit.

**-x**  
**--no-privileges**  
**--no-acl**

Prevent restoration of access privileges (grant/revoke commands).

**-1**  
**--single-transaction**

Execute the restore as a single transaction (that is, wrap the emitted commands in **BEGIN/COMMIT**). This ensures that either all the commands complete successfully, or no changes are applied. This option implies **--exit-on-error**.

**--disable-triggers**

This option is relevant only when performing a restore without schema. It instructs `pg_restore` to execute commands to temporarily disable triggers on the target tables while the data is restored. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data restore.

Presently, the commands emitted for **--disable-triggers** must be done as superuser. So you should also specify a superuser name with **-S** or, preferably, run `pg_restore` as a PostgreSQL superuser.

**--enable-row-security**

This option is relevant only when restoring the contents of a table which has row security. By default, `pg_restore` will set `row_security` to off, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_restore` to set `row_security` to on instead, allowing the user to attempt to restore the contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.

Note that this option currently also requires the dump be in **INSERT** format, as **COPY FROM** does not support row security.

**--filter=filename**

Specify a filename from which to read patterns for objects excluded or included from restore. The patterns are interpreted according to the same rules as `-n/--schema` for including objects in schemas, `-N/--exclude-schema` for excluding objects in schemas, `-P/--function` for restoring named functions, `-I/--index` for restoring named indexes, `-t/--table` for restoring named tables or `-T/--trigger` for restoring triggers. To read from STDIN, use `-` as the filename. The `--filter` option can be specified in conjunction with the above listed options for including or excluding objects, and can also be specified more than once for multiple filter files.

The file lists one database pattern per row, with the following format:

```
{ include | exclude } { function | index | schema | table |  
  trigger } PATTERN
```

The first keyword specifies whether the objects matched by the pattern are to be included or excluded. The second keyword specifies the type of object to be filtered using the pattern:

- **function**: functions, works like the `-P/--function` option. This keyword can only be used with the `include` keyword.
- **index**: indexes, works like the `-I/--indexes` option. This keyword can only be used with the `include` keyword.
- **schema**: schemas, works like the `-n/--schema` and `-N/--exclude-schema` options.
- **table**: tables, works like the `-t/--table` option. This keyword can only be used with the `include` keyword.
- **trigger**: triggers, works like the `-T/--trigger` option. This keyword can only be used with the `include` keyword.

Lines starting with `#` are considered comments and ignored. Comments can be placed after an object pattern row as well. Blank lines are also ignored. See Patterns for how to perform quoting in patterns.

**--if-exists**

Use `DROP ... IF EXISTS` commands to drop objects in `--clean` mode. This suppresses “does not exist” errors that might otherwise be reported. This option is not valid unless `--clean` is also specified.

**--no-comments**

Do not output commands to restore comments, even if the archive contains them.

**--no-data**

Do not output commands to restore data, even if the archive contains them.

**--no-data-for-failed-tables**

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for PostgreSQL extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.

This option is effective only when restoring directly into a database, not when producing SQL script output.

**--no-policies**

Do not output commands to restore row security policies, even if the archive contains them.

**--no-publications**

Do not output commands to restore publications, even if the archive contains them.

**--no-schema**

Do not output commands to restore schema (data definitions), even if the archive contains them.

**--no-security-labels**

Do not output commands to restore security labels, even if the archive contains them.

**--no-statistics**

Do not output commands to restore statistics, even if the archive contains them.

**--no-subscriptions**

Do not output commands to restore subscriptions, even if the archive contains them.

**--no-table-access-method**

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

**--no-tablespaces**

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

**--restrict-key=restrict\_key**

Use the provided string as the `psql \restrict` key in the dump output. This can only be specified for SQL script output, i.e., when the `--file` option is used. If no restrict key is specified, `pg_restore` will generate a random one as needed. Keys may contain only alphanumeric characters.

This option is primarily intended for testing purposes and other scenarios that require repeatable output (e.g., comparing dump files). It is not recommended for general use, as a malicious server with advance knowledge of the key may be able to inject arbitrary code that will be executed on the machine that runs `psql` with the dump output.

**--section=sectionname**

Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to restore all sections.

The data section contains actual table data as well as large-object definitions. Post-data items consist of definitions of indexes, triggers, rules and constraints other than validated check constraints. Pre-data items consist of all other data definition items.

**--statistics**

Output commands to restore statistics, if the archive contains them. This is the default.

**--statistics-only**

Restore only the statistics, not schema (data definitions) or data.

**--strict-names**

Require that each schema (**-n/- -schema**) and table (**-t/- -table**) qualifier match at least one schema/table in the file to be restored.

**--transaction-size=N**

Execute the restore as a series of transactions, each processing up to *N* database objects. This option implies **--exit-on-error**.

**- -transaction-size** offers an intermediate choice between the default behavior (one transaction per SQL command) and **-1/- -single-transaction** (one transaction for all restored objects). While **--single-transaction** has the least overhead, it may be impractical for large databases because the transaction will take a lock on each restored object, possibly exhausting the server's lock table space. Using **- -transaction-size** with a size of a few thousand objects offers nearly the same performance benefits while capping the amount of lock table space needed.

**--use-set-session-authorization**

Output SQL-standard **SET SESSION AUTHORIZATION** commands instead of **ALTER OWNER** commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly.

**-?**

**--help**

Show help about `pg_restore` command line arguments, and exit.

`pg_restore` also accepts the following command line arguments for connection parameters:

**-h *host*****--host=*host***

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the **PGHOST** environment variable, if set, else a Unix domain socket connection is attempted.

**-p *port*****--port=*port***

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the **PGPORT** environment variable, if set, or a compiled-in default.

**-U *username*****--username=*username***

User name to connect as.

**-w****--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a **.pgpass** file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W****--password**

Force `pg_restore` to prompt for a password before connecting to a database.

This option is never essential, since `pg_restore` will automatically prompt for a password if the server demands password authentication. However, `pg_restore` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to perform the restore. This option causes `pg_restore` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_restore`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

## Environment

PGHOST  
PGOPTIONS  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 32.15). However, it does not read `PGDATABASE` when a database name is not supplied.

## Diagnostics

When a direct database connection is specified using the `-d` option, `pg_restore` internally executes SQL statements. If you have problems running `pg_restore`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

## Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

The limitations of `pg_restore` are detailed below.

- When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.
- `pg_restore` cannot restore large objects selectively; for instance, only those for a specific table. If an archive contains large objects, then all large objects will be restored, or none of them if they are excluded via `-L`, `-t`, or other options.

See also the `pg_dump` documentation for details on limitations of `pg_dump`.

By default, `pg_restore` will restore optimizer statistics if included in the dump file. If not all statistics were restored, it may be useful to run `ANALYZE` on each restored table so the optimizer has useful statistics; see Section 24.1.3 and Section 24.1.6 for more information.

## Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
$ pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
$ dropdb mydb
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To restore the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don't use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
;
; Archive created at Mon Sep 14 13:55:39 2009
;   dbname: DBDEMOS
;   TOC Entries: 81
;   Compression: 9
;   Dump Version: 1.10-0
;   Format: CUSTOM
;   Integer: 4 bytes
;   Offset: 8 bytes
;   Dumped from database version: 8.3.5
;   Dumped by pg_dump version: 8.3.8
;
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

# pg\_verifybackup

pg\_verifybackup — verify the integrity of a base backup of a PostgreSQL cluster

## Synopsis

pg\_verifybackup [*option...*]

## Description

pg\_verifybackup is used to check the integrity of a database cluster backup taken using `pg_basebackup` against a `backup_manifest` generated by the server at the time of the backup. The backup may be stored either in the "plain" or the "tar" format; this includes tar-format backups compressed with any algorithm supported by `pg_basebackup`. However, at present, WAL verification is supported only for plain-format backups. Therefore, if the backup is stored in tar-format, the `-n`, `--no-parse-wal` option should be used.

It is important to note that the validation which is performed by `pg_verifybackup` does not and cannot include every check which will be performed by a running server when attempting to make use of the backup. Even if you use this tool, you should still perform test restores and verify that the resulting databases work as expected and that they appear to contain the correct data. However, `pg_verifybackup` can detect many problems that commonly occur due to storage problems or user error.

Backup verification proceeds in four stages. First, `pg_verifybackup` reads the `backup_manifest` file. If that file does not exist, cannot be read, is malformed, fails to match the system identifier with `pg_control` of the backup directory or fails verification against its own internal checksum, `pg_verifybackup` will terminate with a fatal error.

Second, `pg_verifybackup` will attempt to verify that the data files currently stored on disk are exactly the same as the data files which the server intended to send, with some exceptions that are described below. Extra and missing files will be detected, with a few exceptions. This step will ignore the presence or absence of, or any modifications to, `postgresql.auto.conf`, `standby.signal`, and `recovery.signal`, because it is expected that these files may have been created or modified as part of the process of taking the backup. It also won't complain about a `backup_manifest` file in the target directory or about anything inside `pg_wal`, even though these files won't be listed in the backup manifest. Only files are checked; the presence or absence of directories is not verified, except indirectly: if a directory is missing, any files it should have contained will necessarily also be missing.

Next, `pg_verifybackup` will checksum all the files, compare the checksums against the values in the manifest, and emit errors for any files for which the computed checksum does not match the checksum stored in the manifest. This step is not performed for any files which produced errors in the previous step, since they are already known to have problems. Files which were ignored in the previous step are also ignored in this step.

Finally, `pg_verifybackup` will use the manifest to verify that the write-ahead log records which will be needed to recover the backup are present and that they can be read and parsed. The `backup_manifest` contains information about which write-ahead log records will be needed, and `pg_verifybackup` will use that information to invoke `pg_waldump` to parse those write-ahead log records. The `--quiet` flag will be used, so that `pg_waldump` will only report errors, without producing any other output. While this level of verification is sufficient to detect obvious problems such as a missing file or one whose internal checksums do not match, they aren't extensive enough to detect every possible problem that might occur when attempting to recover. For instance, a server bug that produces write-ahead log records that have the correct checksums but specify nonsensical actions can't be detected by this method.

Note that if extra WAL files which are not required to recover the backup are present, they will not be checked by this tool, although a separate invocation of `pg_waldump` could be used for that purpose.

Also note that WAL verification is version-specific: you must use the version of `pg_verifybackup`, and thus of `pg_waldump`, which pertains to the backup being checked. In contrast, the data file integrity checks should work with any version of the server that generates a `backup_manifest` file.

## Options

`pg_verifybackup` accepts the following command-line arguments:

`-e`  
`--exit-on-error`

Exit as soon as a problem with the backup is detected. If this option is not specified, `pg_verifybackup` will continue checking the backup even after a problem has been detected, and will report all problems detected as errors.

`-F format`  
`--format=format`

Specifies the format of the backup. *format* can be one of the following:

`p`  
`plain`

Backup consists of plain files with the same layout as the source server's data directory and tablespaces.

`t`  
`tar`

Backup consists of tar files, which may be compressed. A valid backup includes the main data directory in a file named `base.tar`, the WAL files in `pg_wal.tar`, and separate tar files for each tablespace, named after the tablespace's OID. If the backup is compressed, the relevant compression extension is added to the end of each file name.

`-i path`  
`--ignore=path`

Ignore the specified file or directory, which should be expressed as a relative path name, when comparing the list of data files actually present in the backup to those listed in the `backup_manifest` file. If a directory is specified, this option affects the entire subtree rooted at that location. Complaints about extra files, missing files, file size differences, or checksum mismatches will be suppressed if the relative path name matches the specified path name. This option can be specified multiple times.

`-m path`  
`--manifest-path=path`

Use the manifest file at the specified path, rather than one located in the root of the backup directory.

`-n`  
`--no-parse-wal`

Don't attempt to parse write-ahead log data that will be needed to recover from this backup.

`-P`  
`--progress`

Enable progress reporting. Turning this on will deliver a progress report while verifying checksums.

This option cannot be used together with the option `--quiet`.

`-q`  
`--quiet`

Don't print anything when a backup is successfully verified.

`-S`  
`--skip-checksums`

Do not verify data file checksums. The presence or absence of files and the sizes of those files will still be checked. This is much faster, because the files themselves do not need to be read.

`-w path`  
`--wal-directory=path`

Try to parse WAL files stored in the specified directory, rather than in `pg_wal`. This may be useful if the backup is stored in a separate location from the WAL archive.

Other options are also available:

`-V`  
`--version`

Print the `pg_verifybackup` version and exit.

`-?`  
`--help`

Show help about `pg_verifybackup` command line arguments, and exit.

## Examples

To create a base backup of the server at `mydbserver` and verify the integrity of the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ pg_verifybackup /usr/local/pgsql/data
```

To create a base backup of the server at `mydbserver`, move the manifest somewhere outside the backup directory, and verify the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/backup1234
$ mv /usr/local/pgsql/backup1234/backup_manifest /my/secure/
location/backup_manifest.1234
$ pg_verifybackup -m /my/secure/location/backup_manifest.1234 /usr/
local/pgsql/backup1234
```

To verify a backup while ignoring a file that was added manually to the backup directory, and also skipping checksum verification:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ edit /usr/local/pgsql/data/note.to.self
$ pg_verifybackup --ignore=note.to.self --skip-checksums /usr/
local/pgsql/data
```

# psql

psql — PostgreSQL interactive terminal

## Synopsis

```
psql [option...] [dbname [username]]
```

## Description

psql is a terminal-based front-end to PostgreSQL. It enables you to type in queries interactively, issue them to PostgreSQL, and see the query results. Alternatively, input can be from a file or from command line arguments. In addition, psql provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

## Options

**-a**  
**--echo-all**

Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable `ECHO` to `all`.

**-A**  
**--no-align**

Switches to unaligned output mode. (The default output mode is `aligned`.) This is equivalent to `\pset format unaligned`.

**-b**  
**--echo-errors**

Print failed SQL commands to standard error output. This is equivalent to setting the variable `ECHO` to `errors`.

**-c *command***  
**--command=*command***

Specifies that psql is to execute the given command string, *command*. This option can be repeated and combined in any order with the **-f** option. When either **-c** or **-f** is specified, psql does not read commands from standard input; instead it terminates after processing all the **-c** and **-f** options in sequence.

*command* must be either a command string that is completely parsable by the server (i.e., it contains no psql-specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands within a **-c** option. To achieve that, you could use repeated **-c** options or pipe the string into psql, for example:

```
psql -c '\x' -c 'SELECT * FROM foo;'
```

or

```
echo '\x \ SELECT * FROM foo;' | psql
```

(\\ is the separator meta-command.)

Each SQL command string passed to `-c` is sent to the server as a single request. Because of this, the server executes it as a single transaction even if the string contains multiple SQL commands, unless there are explicit **BEGIN/COMMIT** commands included in the string to divide it into multiple transactions. (See Section 54.2.2.1 for more details about how the server handles multi-query strings.)

If having several commands executed in one transaction is not desired, use repeated `-c` commands or feed multiple commands to psql's standard input, either using echo as illustrated above, or via a shell here-document, for example:

```
psql <<EOF
\x
SELECT * FROM foo;
EOF
```

`--csv`

Switches to CSV (Comma-Separated Values) output mode. This is equivalent to `\pset format csv`.

`-d dbname`

`--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

`-e`

`--echo-queries`

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

`-E`

`--echo-hidden`

Echo the actual queries generated by `\d` and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable `ECHO_HIDDEN` to `on`.

`-f filename`

`--file=filename`

Read commands from the file *filename*, rather than standard input. This option can be repeated and combined in any order with the `-c` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence. Except for that, this option is largely equivalent to the meta-command `\i`.

If *filename* is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note however that Readline is not used in this case (much as if `-n` had been specified).

Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

**-F** *separator*  
**--field-separator=***separator*

Use *separator* as the field separator for unaligned output. This is equivalent to `\pset fieldsep` or `\f`.

**-h** *hostname*  
**--host=***hostname*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

**-H**  
**--html**

Switches to HTML output mode. This is equivalent to `\pset format html` or the `\H` command.

**-l**  
**--list**

List all available databases, then exit. Other non-connection options are ignored. This is similar to the meta-command `\list`.

When this option is used, `psql` will connect to the database `postgres`, unless a different database is named on the command line (option `-d` or non-option argument, possibly via a service entry, but not via an environment variable).

**-L** *filename*  
**--log-file=***filename*

Write all query output into file *filename*, in addition to the normal output destination.

**-n**  
**--no-readline**

Do not use Readline for line editing and do not use the command history (see the section called “Command-Line Editing” below).

**-o** *filename*  
**--output=***filename*

Put all query output into file *filename*. This is equivalent to the command `\o`.

**-p** *port*  
**--port=***port*

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

**-P** *assignment*  
**--pset=***assignment*

Specifies printing options, in the style of `\pset`. Note that here you have to separate name and value with an equal sign instead of a space. For example, to set the output format to LaTeX, you could write `-P format=latex`.

**-q**  
**--quiet**

Specifies that `psql` should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. This is equivalent to setting the variable `QUIET` to `on`.

**-R *separator***  
**--record-separator=*separator***

Use *separator* as the record separator for unaligned output. This is equivalent to `\pset recordsep`.

**-S**  
**--single-step**

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

**-S**  
**--single-line**

Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.

### Note

This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.

**-t**  
**--tuples-only**

Turn off printing of column names and result row count footers, etc. This is equivalent to `\t` or `\pset tuples_only`.

**-T *table\_options***  
**--table-attr=*table\_options***

Specifies options to be placed within the HTML `table` tag. See `\pset tableattr` for details.

**-U *username***  
**--username=*username***

Connect to the database as the user *username* instead of the default. (You must have permission to do so, of course.)

**-v *assignment***  
**--set=*assignment***  
**--variable=*assignment***

Perform a variable assignment, like the `\set` meta-command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during command line processing, so variables that reflect connection state will get overwritten later.

**-V**  
**--version**

Print the psql version and exit.

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available from other sources such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

`-W`  
`--password`

Force psql to prompt for a password before connecting to a database, even if the password will not be used.

If the server requires password authentication and a password is not available from other sources such as a `.pgpass` file, psql will prompt for a password in any case. However, psql will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

`-x`  
`--expanded`

Turn on the expanded table formatting mode. This is equivalent to `\x` or `\pset expanded`.

`-X`  
`--no-psqlrc`

Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).

`-Z`  
`--field-separator-zero`

Set the field separator for unaligned output to a zero byte. This is equivalent to `\pset fieldsep_zero`.

`-0`  
`--record-separator-zero`

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with `xargs -0`. This is equivalent to `\pset recordsep_zero`.

`-1`  
`--single-transaction`

This option can only be used in combination with one or more `-C` and/or `-f` options. It causes psql to issue a `BEGIN` command before the first such option and a `COMMIT` command after the last one, thereby wrapping all the commands into a single transaction. If any of the commands fails and the variable `ON_ERROR_STOP` was set, a `ROLLBACK` command is sent instead. This ensures that either all the commands complete successfully, or no changes are applied.

If the commands themselves contain `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if an individual command cannot be executed inside a transaction block, specifying this option will cause the whole transaction to fail.

`-?`  
`--help[=topic]`

Show help about psql and exit. The optional *topic* parameter (defaulting to `options`) selects which part of psql is explained: `commands` describes psql's backslash commands; `options` describes the command-line options that can be passed to psql; and `variables` shows help about psql configuration variables.

## Exit Status

psql returns 0 to the shell if it finished normally, 1 if a fatal error of its own occurs (e.g., out of memory, file not found), 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

## Usage

### Connecting to a Database

psql is a regular PostgreSQL client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server, and what database user name you want to connect as. psql can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the database user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, psql will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to `localhost` on Windows. The default port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default database user name is your operating-system user name. Once the database user name is determined, it is used as the default database name. Note that you cannot just connect to any database under any database user name. Your database administrator should have informed you about your access rights.

When the defaults aren't quite right, you can save yourself some typing by setting the environment variables `PGDATABASE`, `PGHOST`, `PGPORT` and/or `PGUSER` to appropriate values. (For additional environment variables, see Section 32.15.) It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. See Section 32.16 for more information.

An alternative way to specify connection parameters is in a *conninfo* string or a URI, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://dbmaster:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in Section 32.18. See Section 32.1.2 for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), psql will return an error and terminate.

If both standard input and standard output are a terminal, then psql sets the client encoding to “auto”, which will detect the appropriate client encoding from the locale settings (`LC_CTYPE` environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable `PGCLIENTENCODING`.

### Entering SQL Commands

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string `=>`. For example:

```
$ psql testdb
psql (18.4)
Type "help" for help.

testdb=>
```

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin your session by removing publicly-writable schemas from `search_path`. One can add `options=-csearch_path=` to the connection string or issue `SELECT pg_catalog.set_config('search_path', '', false)` before other SQL commands. This consideration is not specific to psql; it applies to every interface for executing arbitrary SQL commands.

Whenever a command is executed, psql also polls for asynchronous notification events generated by `LISTEN` and `NOTIFY`.

While C-style block comments are passed to the server for processing and removal, SQL-standard comments are removed by psql.

## Meta-Commands

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands make psql more useful for administration or scripting. Meta-commands are often called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace in an argument you can quote it with single quotes. To include a single quote in an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\b` (backspace), `\r` (carriage return), `\f` (form feed), `\digits` (octal), and `\xdigits` (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

If an unquoted colon (`:`) followed by a psql variable name appears within an argument, it is replaced by the variable's value, as described in SQL Interpolation below. The forms `:'variable_name'` and `:"variable_name"` described there work as well. The `{?variable_name}` syntax allows testing whether a variable is defined. It is substituted by `TRUE` or `FALSE`. Escaping the colon with a backslash protects it from substitution.

Within an argument, text that is enclosed in backquotes (```) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text. Within the text enclosed in backquotes, no special quoting or other processing occurs, except that appearances of `:variable_name` where `variable_name` is a psql variable name are replaced by the variable's value. Also, appearances of `:'variable_name'` are replaced by the variable's value suitably quoted to become a single shell command argument. (The latter form is almost always preferable, unless you are very sure of what is in the variable.) Because carriage return and line feed characters cannot be safely quoted on all platforms, the `:'variable_name'` form prints an error message and does not substitute the variable value when such characters appear in the value.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" name"` becomes `A weird name`.

Parsing for arguments stops at the end of the line, or when another unquoted backslash is found. An unquoted backslash is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Many of the meta-commands act on the *current query buffer*. This is simply a buffer holding whatever SQL command text has been typed but not yet sent to the server for execution. This will include previous input lines as well as any text appearing before the meta-command on the same line.

Many of the meta-commands also allow `x` to be appended as an option. This will cause the results to be displayed in expanded mode, as if `\x` or `\pset expanded` had been used.

The following meta-commands are defined:

`\a`

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

`\bind [ parameter ] ...`

Sets query parameters for the next query execution, with the specified parameters passed for any parameter placeholders (`$1` etc.).

Example:

```
INSERT INTO tbl1 VALUES ($1, $2) \bind 'first value' 'second
value' \g
```

This also works for query-execution commands besides `\g`, such as `\gx` and `\gset`.

This command causes the extended query protocol (see Section 54.1.2) to be used, unlike normal psql operation, which uses the simple query protocol. So this command can be useful to test the extended query protocol from psql. (The extended query protocol is used even if the query has no parameters and this command specifies zero parameters.) This command affects only the next query executed; all subsequent queries will use the simple query protocol by default.

`\bind_named statement_name [ parameter ] ...`

`\bind_named` is equivalent to `\bind`, except that it takes the name of an existing prepared statement as first parameter. An empty string denotes the unnamed prepared statement.

Example:

```
INSERT INTO tbls1 VALUES ($1, $2) \parse stmt1
\bind_named stmt1 'first value' 'second value' \g
```

This command causes the extended query protocol (see Section 54.1.2) to be used, unlike normal psql operation, which uses the simple query protocol. So this command can be useful to test the extended query protocol from psql.

`\c` or `\connect [ -reuse-previous=on|off ] [ dbname [ username ] [ host ] [ port ] | conninfo ]`

Establishes a new connection to a PostgreSQL server. The connection parameters to use can be specified either using a positional syntax (one or more of database name, user, host, and port), or using a *conninfo* connection string as detailed in Section 32.1.1. If no arguments are given, a new connection is made using the same parameters as before.

Specifying any of *dbname*, *username*, *host* or *port* as `-` is equivalent to omitting that parameter.

The new connection can re-use connection parameters from the previous connection; not only database name, user, host, and port, but other settings such as *sslmode*. By default, parameters are re-used in the positional syntax, but not when a *conninfo* string is given. Passing a first

argument of `-reuse-previous=on` or `-reuse-previous=off` overrides that default. If parameters are re-used, then any parameter not explicitly specified as a positional parameter or in the *conninfo* string is taken from the existing connection's parameters. An exception is that if the *host* setting is changed from its previous value using the positional syntax, any *hostaddr* setting present in the existing connection's parameters is dropped. Also, any password used for the existing connection will be re-used only if the user, host, and port settings are not changed. When the command neither specifies nor reuses a particular parameter, the libpq default is used.

If the new connection is successfully made, the previous connection is closed. If the connection attempt fails (wrong user name, access denied, etc.), the previous connection will be kept if psql is in interactive mode. But when executing a non-interactive script, the old connection is closed and an error is reported. That may or may not terminate the script; if it does not, all database-accessing commands will fail until another `\connect` command is successfully executed. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand. Note that whenever a `\connect` command attempts to re-use parameters, the values re-used are those of the last successful connection, not of any failed attempts made subsequently. However, in the case of a non-interactive `\connect` failure, no parameters are allowed to be re-used later, since the script would likely be expecting the values from the failed `\connect` to be re-used.

Examples:

```
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10
    sslmode=disable"
=> \c -reuse-previous=on sslmode=require    -- changes only
    sslmode
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```

`\C [ title ]`

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title title`. (The name of this command derives from “caption”, as it was previously only used to set the caption in an HTML table.)

`\cd [ directory ]`

Changes the current working directory to *directory*. Without argument, changes to the current user's home directory. For details on how home directories are found, see Section 32.16.

### Tip

To print your current working directory, use `\! pwd`.

`\close_prepared prepared_statement_name`

Closes the specified prepared statement. An empty string denotes the unnamed prepared statement. If no prepared statement exists with this name, the operation is a no-op.

Example:

```
SELECT $1 \parse stmt1
\close_prepared stmt1
```

This command causes the extended query protocol to be used, unlike normal psql operation, which uses the simple query protocol. So this command can be useful to test the extended query protocol from psql.

## `\conninfo`

Outputs information about the current database connection, including SSL-related information if SSL is in use.

Note that the `Client User` field shows the user at the time of connection, while the `Superuser` field indicates whether the current user (in the current execution context) has superuser privileges. These users are usually the same, but they can differ, for example, if the current user was changed with the `SET ROLE` command.

```
\copy { table [ ( column_list ) ] } from { 'filename' | program
'command' | stdin | pstdin } [ [ with ] ( option [, ...] ) ] [ where
condition ]
\copy { table [ ( column_list ) ] | ( query ) } to { 'filename' |
program 'command' | stdout | pstdout } [ [ with ] ( option [, ...] ) ]
```

Performs a frontend (client) copy. This is an operation that runs an SQL `COPY` command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When `program` is specified, `command` is executed by psql and the data passed from or to `command` is routed between the server and the client. Again, the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

For `\copy ... from stdin`, data rows are read from the same source that issued the command, continuing until a line containing only `\.` is read or the stream reaches EOF. This option is useful for populating tables in-line within an SQL script file. For `\copy ... to stdout`, output is sent to the same place as psql command output, and the `COPY count` command status is not printed (since it might be confused with a data row). To read/write psql's standard input or output regardless of the current command source or `\o` option, write `from pstdin` or `to pstdout`.

The syntax of this command is similar to that of the SQL `COPY` command. All options other than the data source/destination are as specified for `COPY`. Because of this, special parsing rules apply to the `\copy` meta-command. Unlike most other meta-commands, the entire remainder of the line is always taken to be the arguments of `\copy`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Tip

Another way to obtain the same result as `\copy ... to` is to use the SQL `COPY ... TO STDOUT` command and terminate it with `\g filename` or `\g |program`. Unlike `\copy`, this method allows the command to span multiple lines; also, variable interpolation and backquote expansion can be used.

### Tip

These operations are not as efficient as the SQL `COPY` command with a file or program data source or destination, because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable.

## `\copyright`

Shows the copyright and distribution terms of PostgreSQL.

```
\crosstabview [ colV [ colH [ colD [ sortcolH ] ] ] ]
```

Executes the current query buffer (like \g) and shows the results in a crosstab grid. The query must return at least three columns. The output column identified by *colV* becomes a vertical header and the output column identified by *colH* becomes a horizontal header. *colD* identifies the output column to display within the grid. *sortcolH* identifies an optional sort column for the horizontal header.

Each column specification can be a column number (starting at 1) or a column name. The usual SQL case folding and quoting rules apply to column names. If omitted, *colV* is taken as column 1 and *colH* as column 2. *colH* must differ from *colV*. If *colD* is not specified, then there must be exactly three columns in the query result, and the column that is neither *colV* nor *colH* is taken to be *colD*.

The vertical header, displayed as the leftmost column, contains the values found in column *colV*, in the same order as in the query results, but with duplicates removed.

The horizontal header, displayed as the first row, contains the values found in column *colH*, with duplicates removed. By default, these appear in the same order as in the query results. But if the optional *sortcolH* argument is given, it identifies a column whose values must be integer numbers, and the values from *colH* will appear in the horizontal header sorted according to the corresponding *sortcolH* values.

Inside the crosstab grid, for each distinct value *x* of *colH* and each distinct value *y* of *colV*, the cell located at the intersection (*x*, *y*) contains the value of the *colD* column in the query result row for which the value of *colH* is *x* and the value of *colV* is *y*. If there is no such row, the cell is empty. If there are multiple such rows, an error is reported.

```
\d[Sx+] [ pattern ]
```

For each relation (table, view, materialized view, index, sequence, or foreign table) or composite type matching the *pattern*, show all columns, their types, the tablespace (if not the default) and any special attributes such as NOT NULL or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well. (“Matching the pattern” is defined in Patterns below.)

For some types of relation, \d shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.

The command form \d+ is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view, a non-default replica identity setting and the access method name if the relation has an access method.

By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

### Note

If \d is used without a *pattern* argument, it is equivalent to \dtvmsE which will show a list of all visible tables, views, materialized views, sequences and foreign tables. This is purely a convenience measure.

As with many other commands, if *x* is appended to the command name, the results are displayed in expanded mode, but note that this only applies when \d is used without a *pattern* argument, and the *x* modifier cannot appear immediately after the \d (because \dx is a different command); the *x* modifier may only appear after an S or + modifier. For example, \d+x is equivalent to \dtvmsE+x and will show a list of all relations in expanded mode.

`\da[Sx] [ pattern ]`

Lists aggregate functions, together with their return type and the data types they operate on. If *pattern* is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the **S** modifier to include system objects. If **x** is appended to the command name, the results are displayed in expanded mode.

`\dA[x+] [ pattern ]`

Lists access methods. If *pattern* is specified, only access methods whose names match the pattern are shown. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each access method is listed with its associated handler function and description.

`\dAc[x+] [ access-method-pattern [ input-type-pattern ]`

Lists operator classes (see Section 36.16.1). If *access-method-pattern* is specified, only operator classes associated with access methods whose names match that pattern are listed. If *input-type-pattern* is specified, only operator classes associated with input types whose names match that pattern are listed. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each operator class is listed with its associated operator family and owner.

`\dAf[x+] [ access-method-pattern [ input-type-pattern ]`

Lists operator families (see Section 36.16.5). If *access-method-pattern* is specified, only operator families associated with access methods whose names match that pattern are listed. If *input-type-pattern* is specified, only operator families associated with input types whose names match that pattern are listed. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each operator family is listed with its owner.

`\dAo[x+] [ access-method-pattern [ operator-family-pattern ]`

Lists operators associated with operator families (see Section 36.16.2). If *access-method-pattern* is specified, only members of operator families associated with access methods whose names match that pattern are listed. If *operator-family-pattern* is specified, only members of operator families whose names match that pattern are listed. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each operator is listed with its sort operator family (if it is an ordering operator), and whether its underlying function is leakproof.

`\dAp[x+] [ access-method-pattern [ operator-family-pattern ]`

Lists support functions associated with operator families (see Section 36.16.3). If *access-method-pattern* is specified, only functions of operator families associated with access methods whose names match that pattern are listed. If *operator-family-pattern* is specified, only functions of operator families whose names match that pattern are listed. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, functions are displayed verbosely, with their actual parameter lists.

`\db[x+] [ pattern ]`

Lists tablespaces. If *pattern* is specified, only tablespaces whose names match the pattern are shown. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each tablespace is listed with its associated options, on-disk size, permissions and description.

`\dc[Sx+] [ pattern ]`

Lists conversions between character-set encodings. If *pattern* is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply

a pattern or the **S** modifier to include system objects. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each object is listed with its associated description.

**\dconfig[x+] [ *pattern* ]**

Lists server configuration parameters and their values. If *pattern* is specified, only parameters whose names match the pattern are listed. Without a *pattern*, only parameters that are set to non-default values are listed. (Use **\dconfig \*** to see all parameters.) If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each parameter is listed with its data type, context in which the parameter can be set, and access privileges (if non-default access privileges have been granted).

**\dC[x+] [ *pattern* ]**

Lists type casts. If *pattern* is specified, only casts whose source or target types match the pattern are listed. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, additional information about each cast is shown, including whether its underlying function is leakproof, and the cast's description.

**\dd[Sx] [ *pattern* ]**

Shows the descriptions of objects of type **constraint**, **operator class**, **operator family**, **rule**, and **trigger**. All other comments may be viewed by the respective backslash commands for those object types.

**\dd** displays descriptions for objects matching the *pattern*, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the **S** modifier to include system objects. If **x** is appended to the command name, the results are displayed in expanded mode.

Descriptions for objects can be created with the **COMMENT SQL** command.

**\dD[Sx+] [ *pattern* ]**

Lists domains. If *pattern* is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the **S** modifier to include system objects. If **x** is appended to the command name, the results are displayed in expanded mode. If **+** is appended to the command name, each object is listed with its associated permissions and description.

**\ddp[x] [ *pattern* ]**

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If *pattern* is specified, only entries whose role name or schema name matches the pattern are listed. If **x** is appended to the command name, the results are displayed in expanded mode.

The **ALTER DEFAULT PRIVILEGES** command is used to set default access privileges. The meaning of the privilege display is explained in Section 5.8.

**\dE[Sx+] [ *pattern* ]**

**\di[Sx+] [ *pattern* ]**

**\dm[Sx+] [ *pattern* ]**

**\ds[Sx+] [ *pattern* ]**

**\dt[Sx+] [ *pattern* ]**

**\dv[Sx+] [ *pattern* ]**

In this group of commands, the letters **E**, **i**, **m**, **S**, **t**, and **v** stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, **\dti** lists tables and in-

dexes. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, each object is listed with its persistence status (permanent, temporary, or unlogged), physical size on disk, and associated description if any. If *pattern* is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *S* modifier to include system objects.

`\des[x+] [ pattern ]`

Lists foreign servers (mnemonic: “external servers”). If *pattern* is specified, only those servers whose name matches the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, a full description of each server is shown, including the server’s access privileges, type, version, options, and description.

`\det[x+] [ pattern ]`

Lists foreign tables (mnemonic: “external tables”). If *pattern* is specified, only entries whose table name or schema name matches the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, generic options and the foreign table description are also displayed.

`\deu[x+] [ pattern ]`

Lists user mappings (mnemonic: “external users”). If *pattern* is specified, only those mappings whose user names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, additional information about each mapping is shown.

### Caution

`\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.

`\dew[x+] [ pattern ]`

Lists foreign-data wrappers (mnemonic: “external wrappers”). If *pattern* is specified, only those foreign-data wrappers whose name matches the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, the access privileges, options, and description of the foreign-data wrapper are also shown.

`\df[anptwSx+] [ pattern [ arg_pattern ... ] ]`

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “procedure”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters *a*, *n*, *p*, *t*, or *w* to the command. If *pattern* is specified, only functions whose names match the pattern are shown. Any additional arguments are type-name patterns, which are matched to the type names of the first, second, and so on arguments of the function. (Matching functions can have more arguments than what you specify. To prevent that, write a dash - as the last *arg\_pattern*.) By default, only user-created objects are shown; supply a pattern or the *S* modifier to include system objects. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, additional information about each function is shown, including volatility, parallel safety, owner, security classification, whether it is leakproof, access privileges, language, internal name (for C and internal functions only), and description. Source code for a specific function can be seen using `\sf`.

`\dF[x+] [ pattern ]`

Lists text search configurations. If *pattern* is specified, only configurations whose names match the pattern are shown. If *x* is appended to the command name, the results are displayed in

expanded mode. If + is appended to the command name, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

`\dFd[x+] [ pattern ]`

Lists text search dictionaries. If *pattern* is specified, only dictionaries whose names match the pattern are shown. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

`\dFp[x+] [ pattern ]`

Lists text search parsers. If *pattern* is specified, only parsers whose names match the pattern are shown. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

`\dFt[x+] [ pattern ]`

Lists text search templates. If *pattern* is specified, only templates whose names match the pattern are shown. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, additional information is shown about each template, including the underlying function names.

`\dg[Sx+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\du`.) By default, only user-created roles are shown; supply the S modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, additional information is shown about each role; currently this adds the comment for each role.

`\dl[x+]`

This is an alias for `\lo_list`, which shows a list of large objects. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, each large object is listed with its associated permissions, if any.

`\dL[Sx+] [ pattern ]`

Lists procedural languages. If *pattern* is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the S modifier to include system objects. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

`\dn[Sx+] [ pattern ]`

Lists schemas (namespaces). If *pattern* is specified, only schemas whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, each object is listed with its associated permissions and description, if any.

`\do[Sx+] [ pattern [ arg_pattern [ arg_pattern ] ] ]`

Lists operators with their operand and result types. If *pattern* is specified, only operators whose names match the pattern are listed. If one *arg\_pattern* is specified, only prefix operators whose right argument's type name matches that pattern are listed. If two *arg\_patterns* are

specified, only binary operators whose argument type names match those patterns are listed. (Alternatively, write - for the unused argument of a unary operator.) By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, additional information about each operator is shown, including the name of the underlying function, and whether it is leakproof.

`\dO[Sx+] [ pattern ]`

Lists collations. If *pattern* is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects. If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

`\dp[Sx] [ pattern ]`

Lists tables, views and sequences with their associated access privileges. If *pattern* is specified, only tables, views and sequences whose names match the pattern are listed. By default only user-created objects are shown; supply a pattern or the S modifier to include system objects. If x is appended to the command name, the results are displayed in expanded mode.

The GRANT and REVOKE commands are used to set access privileges. The meaning of the privilege display is explained in Section 5.8.

`\dP[itnx+] [ pattern ]`

Lists partitioned relations. If *pattern* is specified, only entries whose name matches the pattern are listed. The modifiers t (tables) and i (indexes) can be appended to the command, filtering the kind of relations to list. By default, partitioned tables and indexes are listed.

If the modifier n (“nested”) is used, or a pattern is specified, then non-root partitioned relations are included, and a column is shown displaying the parent of each partitioned relation.

If x is appended to the command name, the results are displayed in expanded mode. If + is appended to the command name, the sum of the sizes of each relation's partitions is also displayed, along with the relation's description. If n is combined with +, two sizes are shown: one including the total size of directly-attached leaf partitions, and another showing the total size of all partitions, including indirectly attached sub-partitions.

`\drds[x] [ role-pattern [ database-pattern ] ]`

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. *role-pattern* and *database-pattern* are used to select specific roles and databases to list, respectively. If omitted, or if \* is specified, all settings are listed, including those not role-specific or database-specific, respectively. If x is appended to the command name, the results are displayed in expanded mode.

The ALTER ROLE and ALTER DATABASE commands are used to define per-role and per-database configuration settings.

`\drg[Sx] [ pattern ]`

Lists information about each granted role membership, including assigned options (ADMIN, INHERIT and/or SET) and grantor. See the GRANT command for information about role memberships.

By default, only grants to user-created roles are shown; supply the S modifier to include system roles. If *pattern* is specified, only grants to those roles whose names match the pattern are listed. If x is appended to the command name, the results are displayed in expanded mode.

`\dRp[x+] [ pattern ]`

Lists replication publications. If *pattern* is specified, only those publications whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, the tables and schemas associated with each publication are shown as well.

`\dRs[x+] [ pattern ]`

Lists replication subscriptions. If *pattern* is specified, only those subscriptions whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, additional properties of the subscriptions are shown.

`\dT[Sx+] [ pattern ]`

Lists data types. If *pattern* is specified, only types whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the *S* modifier to include system objects.

`\du[Sx+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\dg`.) By default, only user-created roles are shown; supply the *S* modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, additional information is shown about each role; currently this adds the comment for each role.

`\dx[x+] [ pattern ]`

Lists installed extensions. If *pattern* is specified, only those extensions whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, all the objects belonging to each matching extension are listed.

`\dX[x] [ pattern ]`

Lists extended statistics. If *pattern* is specified, only those extended statistics whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode.

The status of each kind of extended statistics is shown in a column named after its statistic kind (e.g. `Ndistinct`). `defined` means that it was requested when creating the statistics, and `NULL` means it wasn't requested. You can use `pg_stats_ext` if you'd like to know whether `ANALYZE` was run and statistics are available to the planner.

`\dy[x+] [ pattern ]`

Lists event triggers. If *pattern* is specified, only those event triggers whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, each object is listed with its associated description.

`\e or \edit [ filename ] [ line_number ]`

If *filename* is specified, the file is edited; after the editor exits, the file's content is copied into the current query buffer. If no *filename* is given, the current query buffer is copied to a temporary file which is then edited in the same fashion. Or, if the current query buffer is empty, the most recently executed query is copied to a temporary file and edited in the same fashion.

If you edit a file or the previous query, and you quit the editor without modifying the file, the query buffer is cleared. Otherwise, the new contents of the query buffer are re-parsed according to the normal rules of psql, treating the whole buffer as a single line. Any complete queries are immediately executed; that is, if the query buffer contains or ends with a semicolon, everything up to that point is executed and removed from the query buffer. Whatever remains in the query buffer is redisplayed. Type semicolon or `\g` to send it, or `\r` to cancel it by clearing the query buffer.

Treating the buffer as a single line primarily affects meta-commands: whatever is in the buffer after a meta-command will be taken as argument(s) to the meta-command, even if it spans multiple lines. (Thus you cannot make meta-command-using scripts this way. Use `\i` for that.)

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

### Tip

See Environment, below, for how to configure and customize your editor.

`\echo text [ ... ]`

Prints the evaluated arguments to standard output, separated by spaces and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo `date`  
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted `-n` the trailing newline is not written (nor is the first argument).

### Tip

If you use the `\O` command to redirect your query output you might wish to use `\qecho` instead of this command. See also `\warn`.

`\ef [ function_description [ line_number ] ]`

This command fetches and edits the definition of the named function or procedure, in the form of a `CREATE OR REPLACE FUNCTION` or `CREATE OR REPLACE PROCEDURE` command. Editing is done in the same way as for `\edit`. If you quit the editor without saving, the statement is discarded. If you save and exit the editor, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ef`, and neither variable interpolation nor backquote expansion are performed in the arguments.

**Tip**

See Environment, below, for how to configure and customize your editor.

`\encoding [ encoding ]`

Sets the client character set encoding. Without an argument, this command shows the current encoding.

`\errverbose`

Repeats the most recent server error message at maximum verbosity, as though `VERBOSITY` were set to `verbose` and `SHOW_CONTEXT` were set to `always`.

`\ev [ view_name [ line_number ] ]`

This command fetches and edits the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. Editing is done in the same way as for `\edit`. If you quit the editor without saving, the statement is discarded. If you save and exit the editor, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or `\g` to send it, or `\r` to cancel.

If no view is specified, a blank `CREATE VIEW` template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the view definition.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ev`, and neither variable interpolation nor backquote expansion are performed in the arguments.

`\f [ string ]`

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). It is equivalent to `\pset fieldsep`.

`\g [ (option=value [...]) ] [ filename ]`  
`\g [ (option=value [...]) ] [ |command ]`

Sends the current query buffer to the server for execution.

If parentheses appear after `\g`, they surround a space-separated list of *option=value* formatting-option clauses, which are interpreted in the same way as `\pset option value` commands, but take effect only for the duration of this query. In this list, spaces are not allowed around `=` signs, but are required between option clauses. If *=value* is omitted, the named *option* is changed in the same way as for `\pset option` with no explicit *value*.

If a *filename* or *|command* argument is given, the query's output is written to the named file or piped to the given shell command, instead of displaying it as usual. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

If the current query buffer is empty, the most recently sent query is re-executed instead. Except for that behavior, `\g` without any arguments is essentially equivalent to a semicolon. With arguments, `\g` provides a “one-shot” alternative to the `\O` command, and additionally allows one-shot adjustments of the output formatting options normally set by `\pset`.

When the last argument begins with `|`, the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

**\gdesc**

Shows the description (that is, the column names and data types) of the result of the current query buffer. The query is not actually executed; however, if it contains some type of syntax error, that error will be reported in the normal way.

If the current query buffer is empty, the most recently sent query is described instead.

**\getenv *psql\_var env\_var***

Gets the value of the environment variable *env\_var* and assigns it to the psql variable *psql\_var*. If *env\_var* is not defined in the psql process's environment, *psql\_var* is not changed. Example:

```
=> \getenv home HOME
=> \echo :home
/home/postgres
```

**\gexec**

Sends the current query buffer to the server, then treats each column of each row of the query's output (if any) as an SQL statement to be executed. For example, to create an index on each column of *my\_table*:

```
=> SELECT format('create index on my_table(%I)', attname)
-> FROM pg_attribute
-> WHERE attrelid = 'my_table'::regclass AND attnum > 0
-> ORDER BY attnum
-> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right within each row if there is more than one column. NULL fields are ignored. The generated queries are sent literally to the server for processing, so they cannot be psql meta-commands nor contain psql variable references. If any individual query fails, execution of the remaining queries continues unless **ON\_ERROR\_STOP** is set. Execution of each query is subject to **ECHO** processing. (Setting **ECHO** to **all** or **queries** is often advisable when using **\gexec**.) Query logging, single-step mode, timing, and other query execution features apply to each generated query as well.

If the current query buffer is empty, the most recently sent query is re-executed instead.

**\gset [ *prefix* ]**

Sends the current query buffer to the server and stores the query's output into psql variables (see Variables below). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a *prefix*, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

If the current query buffer is empty, the most recently sent query is re-executed instead.

```
\gx [ (option=value [...]) ] [ filename ]
\gx [ (option=value [...]) ] [ |command ]
```

\gx is equivalent to \g, except that it forces expanded output mode for this query, as if `expanded=on` were included in the list of \pset options. See also \x.

\h or \help [ *command* ]

Gives syntax help on the specified SQL command. If *command* is not specified, then psql will list all the commands for which syntax help is available. If *command* is an asterisk (\*), then syntax help on all SQL commands is shown.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \help, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Note

To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type **\help alter table**.

\H or \html

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see \pset about setting other output options.

\i or \include *filename*

Reads input from the file *filename* and executes it as though it had been typed on the keyboard.

If *filename* is - (hyphen), then standard input is read until an EOF indication or \q meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

### Note

If you want to see the lines on the screen as they are read you must set the variable ECHO to all.

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks. A conditional block must begin with an \if and end with an \endif. In between there may be any number of \elif clauses,

which may optionally be followed by a single `\else` clause. Ordinary queries and other types of backslash commands may (and usually do) appear between the commands forming a conditional block.

The `\if` and `\elif` commands read their argument(s) and evaluate them as a Boolean expression. If the expression yields `true` then processing continues normally; otherwise, lines are skipped until a matching `\elif`, `\else`, or `\endif` is reached. Once an `\if` or `\elif` test has succeeded, the arguments of later `\elif` commands in the same block are not evaluated but are treated as false. Lines following an `\else` are processed only if no earlier matching `\if` or `\elif` succeeded.

The *expression* argument of an `\if` or `\elif` command is subject to variable interpolation and backquote expansion, just like any other backslash command argument. After that it is evaluated like the value of an on/off option variable. So a valid value is any unambiguous case-insensitive match for one of: `true`, `false`, `1`, `0`, `on`, `off`, `yes`, `no`. For example, `t`, `T`, and `tR` will all be considered to be `true`.

Expressions that do not properly evaluate to true or false will generate a warning and be treated as false.

Lines being skipped are parsed normally to identify queries and backslash commands, but queries are not sent to the server, and backslash commands other than conditionals (`\if`, `\elif`, `\else`, `\endif`) are ignored. Conditional commands are checked only for valid nesting. Variable references in skipped lines are not expanded, and backquote expansion is not performed either.

All the backslash commands of a given conditional block must appear in the same source file. If EOF is reached on the main input file or an `\include`-ed file before all local `\if`-blocks have been closed, then psql will raise an error.

Here is an example:

```
-- check for the existence of two separate records in the
-- database and store
-- the results in separate psql variables
SELECT
    EXISTS(SELECT 1 FROM customer WHERE customer_id = 123) as
    is_customer,
    EXISTS(SELECT 1 FROM employee WHERE employee_id = 456) as
    is_employee
\gset
\if :is_customer
    SELECT * FROM customer WHERE customer_id = 123;
\elif :is_employee
    \echo 'is not a customer but is an employee'
    SELECT * FROM employee WHERE employee_id = 456;
\else
    \if yes
        \echo 'not a customer or employee'
    \else
        \echo 'this will never print'
    \endif
\endif
```

`\ir` or `\include_relative filename`

The `\ir` command is similar to `\i`, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

`\l[x+] or \list[x+] [ pattern ]`

List the databases in the server and show their names, owners, character set encodings, and access privileges. If *pattern* is specified, only databases whose names match the pattern are listed. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

`\lo_export loid filename`

Reads the large object with OID *loid* from the database and writes it to *filename*. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

**Tip**

Use `\lo_list` to find out the large object's OID.

`\lo_import filename [ comment ]`

Stores the file into a PostgreSQL large object. Optionally, it associates the given comment with the object. Example:

```
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of
me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the `\lo_list` command.

Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

`\lo_list[x+]`

Shows a list of all PostgreSQL large objects currently stored in the database, along with any comments provided for them. If *x* is appended to the command name, the results are displayed in expanded mode. If *+* is appended to the command name, each large object is listed with its associated permissions, if any.

`\lo_unlink loid`

Deletes the large object with OID *loid* from the database.

**Tip**

Use `\lo_list` to find out the large object's OID.

`\o or \out [ filename ]`

`\o or \out [ |command ]`

Arranges to save future query results to the file *filename* or pipe future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`); but not error messages.

### Tip

To intersperse text output in between query results, use `\qecho`.

### `\p` or `\print`

Print the current query buffer to the standard output. If the current query buffer is empty, the most recently executed query is printed instead.

### `\parse statement_name`

Creates a prepared statement from the current query buffer, based on the name of a destination prepared-statement object. An empty string denotes the unnamed prepared statement.

Example:

```
SELECT $1 \parse stmt1
```

This command causes the extended query protocol to be used, unlike normal psql operation, which uses the simple query protocol. A Parse (F) message will be issued by this command so it can be useful to test the extended query protocol from psql. This command affects only the next query executed; all subsequent queries will use the simple query protocol by default.

### `\password [ username ]`

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

### `\prompt [ text ] name`

Prompts the user to supply text, which is assigned to the variable *name*. An optional prompt string, *text*, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

### `\pset [ option [ value ] ]`

This command sets options affecting the output of query result tables. *option* indicates which option is to be set. The semantics of *value* vary depending on the selected option. For some options, omitting *value* causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting *value* just results in the current setting being displayed.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

## border

The *value* must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the `border=...` attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same as `border = 2`. The `latex` and `latex-longtable` formats additionally allow a value of 3 to add dividing lines between data rows.

## columns

Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the `wrapped` format only affects screen output. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

## csv\_fieldsep

Specifies the field separator to be used in CSV output format. If the separator character appears in a field's value, that field is output within double quotes, following standard CSV rules. The default is a comma.

## expanded (or x)

If *value* is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If *value* is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the auto setting, the expanded mode is used whenever the query output has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

## fieldsep

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

## fieldsep\_zero

Sets the field separator to use in unaligned output format to a zero byte.

## footer

If *value* is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If *value* is omitted the command toggles footer display on or off.

## format

Sets the output format to one of `aligned`, `asciidoc`, `csv`, `html`, `latex`, `latex-longtable`, `troff-ms`, `unaligned`, or `wrapped`. Unique abbreviations are allowed.

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

**unaligned** format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs, for example, tab-separated or comma-separated format. However, the field separator character is not treated specially if it appears in a column's value; so CSV format may be better suited for such purposes.

CSV format writes column values separated by commas, applying the quoting rules described in RFC 4180<sup>1</sup>. This output is compatible with the CSV format of the server's `COPY` command. A header line with column names is generated unless the `tuples_only` parameter is `on`. Titles and footers are not printed. Each row is terminated by the system-dependent end-of-line character, which is typically a single newline (`\n`) for Unix-like systems or a carriage return and newline sequence (`\r\n`) for Microsoft Windows. Field separator characters other than comma can be selected with `\pset csv_fieldsep`.

**wrapped** format is like **aligned** but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, **wrapped** format behaves the same as **aligned** if the total width needed for column headers exceeds the target.

The `asciidoc`, `html`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. The `latex` format uses LaTeX's `tabular` environment. The `latex-longtable` format requires the LaTeX `longtable` and `booktabs` packages.

## linestyle

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the **aligned** and **wrapped** output formats.

`ascii` style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the **wrapped** format wraps data from one line to the next without a newline character, a dot (`.`) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, the `linestyle` option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

## null

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'`.

---

<sup>1</sup> <https://datatracker.ietf.org/doc/html/rfc4180>

### numericlocale

If *value* is specified it must be either **on** or **off** which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If *value* is omitted the command toggles between regular and locale-specific numeric output.

### pager

Controls use of a pager program for query and psql help output. When the **pager** option is **off**, the pager program is not used. When the **pager** option is **on**, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The **pager** option can also be set to **always**, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. **\pset pager** without a *value* toggles pager use on and off.

If the environment variable **PSQL\_PAGER** or **PAGER** is set, output to be paged is piped to the specified program. Otherwise a platform-dependent default program (such as **more**) is used.

When using the **\watch** command to execute a query repeatedly, the environment variable **PSQL\_WATCH\_PAGER** is used to find the pager program instead, on Unix systems. This is configured separately because it may confuse traditional pagers, but can be used to send output to tools that understand psql's output format (such as **pspg --stream**).

### pager\_min\_lines

If **pager\_min\_lines** is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

### recordsep

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

### recordsep\_zero

Sets the record separator to use in unaligned output format to a zero byte.

### tableattr (or T)

In HTML format, this specifies attributes to be placed inside the **table** tag. This could for example be **cellpadding** or **bgcolor**. Note that you probably don't want to specify **border** here, as that is already taken care of by **\pset border**. If no *value* is given, the table attributes are unset.

In **latex-longtable** format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g., **'0.2 0.2 0.6'**. Unspecified output columns use the last specified value.

### title (or C)

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no *value* is given, the title is unset.

### tuples\_only (or t)

If *value* is specified it must be either **on** or **off** which will enable or disable tuples-only mode. If *value* is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

**unicode\_border\_linestyle**

Sets the border drawing style for the `unicode` line style to one of `single` or `double`.

**unicode\_column\_linestyle**

Sets the column drawing style for the `unicode` line style to one of `single` or `double`.

**unicode\_header\_linestyle**

Sets the header drawing style for the `unicode` line style to one of `single` or `double`.

**xheader\_width**

Sets the maximum width of the header for expanded output to one of `full` (the default value), `column`, `page`, or an *integer value*.

`full`: the expanded header is not truncated, and will be as wide as the widest output line.

`column`: truncate the header line to the width of the first column.

`page`: truncate the header line to the terminal width.

*integer value*: specify the exact maximum width of the header line.

Illustrations of how these different formats look can be seen in Examples, below.

**Tip**

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.

**\q or \quit**

Quits the `psql` program. In a script file, only execution of that script is terminated.

**\qecho *text* [ ... ]**

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\O`.

**\r or \reset**

Resets (clears) the query buffer.

**\restrict *restrict\_key***

Enter "restricted" mode with the provided key. In this mode, the only allowed meta-command is `\unrestrict`, to exit restricted mode. The key may contain only alphanumeric characters.

This command is primarily intended for use in plain-text dumps generated by `pg_dump`, `pg_dumpall`, and `pg_restore`, but it may be useful elsewhere.

**\s [ *filename* ]**

Print `psql`'s command line history to *filename*. If *filename* is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if `psql` was built without Readline support.

**\set [ *name* [ *value* [ ... ] ] ]**

Sets the `psql` variable *name* to *value*, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set to an empty-string value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See Variables below for details. Variable names are case-sensitive.

Certain variables are special, in that they control psql's behavior or are automatically set to reflect connection state. These variables are documented in Variables, below.

### Note

This command is unrelated to the SQL command SET.

`\setenv name [ value ]`

Sets the environment variable *name* to *value*, or if the *value* is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

`\sf[+] function_description`

This command fetches and shows the definition of the named function or procedure, in the form of a `CREATE OR REPLACE FUNCTION` or `CREATE OR REPLACE PROCEDURE` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sf`, and neither variable interpolation nor backquote expansion are performed in the arguments.

`\sv[+] view_name`

This command fetches and shows the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. The definition is printed to the current query output channel, as set by `\o`.

If `+` is appended to the command name, then the output lines are numbered from 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sv`, and neither variable interpolation nor backquote expansion are performed in the arguments.

```
\startpipeline
\sendpipeline
\syncpipeline
\endpipeline
\flushrequest
\flush
\getresults [ number_results ]
```

This group of commands implements pipelining of SQL statements. A pipeline must begin with a `\startpipeline` and end with an `\endpipeline`. In between there may be any number of

`\syncpipeline` commands, which sends a sync message without ending the ongoing pipeline and flushing the send buffer. In pipeline mode, statements are sent to the server without waiting for the results of previous statements. See Section 32.5 for more details.

All queries executed while a pipeline is ongoing use the extended query protocol. Queries are appended to the pipeline when ending with a semicolon. The meta-commands `\bind`, `\bind_named`, `\close_prepared` or `\parse` can be used in an ongoing pipeline. While a pipeline is ongoing, `\sendpipeline` will append the current query buffer to the pipeline. Other meta-commands like `\g`, `\gx` or `\gdesc` are not allowed in pipeline mode.

`\flushrequest` appends a flush command to the pipeline, allowing to read results with `\getresults` without issuing a sync or ending the pipeline. `\getresults` will automatically push unsent data to the server. `\flush` can be used to manually push unsent data.

`\getresults` accepts an optional *number\_results* parameter. If provided, only the first *number\_results* pending results will be read. If not provided or 0, all pending results are read.

When pipeline mode is active, a dedicated prompt variable is available to report the pipeline status. See %P for more details

COPY is not supported while in pipeline mode.

Example:

```
\startpipeline
SELECT * FROM pg_class;
SELECT 1 \bind \sendpipeline
\flushrequest
\getresults
\endpipeline
```

`\t`

Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.

`\T table_options`

Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`.

`\timing [ on | off ]`

With a parameter, turns displaying of how long each SQL statement takes on or off. Without a parameter, toggles the display between on and off. The display is in milliseconds; intervals longer than 1 second are also shown in minutes:seconds format, with hours and days fields added if needed.

`\unrestrict restrict_key`

Exit "restricted" mode (i.e., where all other meta-commands are blocked), provided the specified key matches the one given to `\restrict` when restricted mode was entered.

This command is primarily intended for use in plain-text dumps generated by `pg_dump`, `pg_dumpall`, and `pg_restore`, but it may be useful elsewhere.

`\unset name`

Unsets (deletes) the psql variable *name*.

Most variables that control psql's behavior cannot be unset; instead, an `\unset` command is interpreted as setting them to their default values. See Variables below.

`\w` or `\write filename`  
`\w` or `\write |command`

Writes the current query buffer to the file *filename* or pipes it to the shell command *command*. If the current query buffer is empty, the most recently executed query is written instead.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

`\warn text [ ... ]`

This command is identical to `\echo` except that the output will be written to psql's standard error channel, rather than standard output.

`\watch [ i[interval]=seconds ] [ c[ount]=times ] [ m[in_rows]=rows  
] [ seconds ]`

Repeatedly execute the current query buffer (as `\g` does) until interrupted, or the query fails, or the execution count limit (if given) is reached, or the query no longer returns the minimum number of rows. Wait the specified number of seconds (default 2) between executions. The default wait can be changed with the variable `WATCH_INTERVAL`. For backwards compatibility, *seconds* can be specified with or without an `interval=` prefix. Each query result is displayed with a header that includes the `\pset title` string (if any), the time as of query start, and the delay interval.

If the current query buffer is empty, the most recently sent query is re-executed instead.

`\x [ on | off | auto ]`

Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

`\z[Sx] [ pattern ]`

Lists tables, views and sequences with their associated access privileges. If a *pattern* is specified, only tables, views and sequences whose names match the pattern are listed. By default only user-created objects are shown; supply a pattern or the `S` modifier to include system objects. If `x` is appended to the command name, the results are displayed in expanded mode.

This is an alias for `\dp` ("display privileges").

`\! [ command ]`

With no argument, escapes to a sub-shell; psql resumes when the sub-shell exits. With an argument, executes the shell command *command*.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\!`, and neither variable interpolation nor backquote expansion are performed in the arguments. The rest of the line is simply passed literally to the shell.

`\? [ topic ]`

Shows help information. The optional *topic* parameter (defaulting to `commands`) selects which part of psql is explained: `commands` describes psql's backslash commands; `options` describes the command-line options that can be passed to psql; and `variables` shows help about psql configuration variables.

`\;`

Backslash-semicolon is not a meta-command in the same way as the preceding commands; rather, it simply causes a semicolon to be added to the query buffer without any further processing.

Normally, psql will dispatch an SQL command to the server as soon as it reaches the command-ending semicolon, even if more input remains on the current line. Thus for example entering

```
select 1; select 2; select 3;
```

will result in the three SQL commands being individually sent to the server, with each one's results being displayed before continuing to the next command. However, a semicolon entered as `\;` will not trigger command processing, so that the command before it and the one after are effectively combined and sent to the server in one request. So for example

```
select 1\; select 2\; select 3;
```

results in sending the three SQL commands to the server in a single request, when the non-backslashed semicolon is reached. The server executes such a request as a single transaction, unless there are explicit **BEGIN/COMMIT** commands included in the string to divide it into multiple transactions. (See Section 54.2.2.1 for more details about how the server handles multi-query strings.)

## Patterns

The various `\d` commands accept a *pattern* parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO"BAR"` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be *visible* if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A relation pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally. A relation pattern that contains two dots (`..`) is interpreted as a database name followed by a schema name pattern followed by an object name pattern. The database name portion will not be treated as a pattern and must match the name of the currently connected database, else an error will be raised.

A schema pattern that contains a dot (`.`) is interpreted as a database name followed by a schema name pattern. For example, `\dn mydb.foo*` displays all schemas whose schema name includes `foo`. The database name portion will not be treated as a pattern and must match the name of the currently connected database, else an error will be raised.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in Section 9.7.3, except

for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.`, `*`, `?` which is translated to `.`, and `$` which is matched literally. You can emulate these pattern characters at need by writing `?` for `.`, `(R+|)` for `R*`, or `(R|)` for `R?`. `$` is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, `$` is automatically appended to your pattern). Write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

## Advanced Features

### Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in SQL Interpolation, below.

If you call `\set` without a second argument, the variable is set to an empty-string value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

#### Note

The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

Variables that control psql's behavior generally cannot be unset or set to invalid values. An `\unset` command is allowed but is interpreted as setting the variable to its default value. A `\set` command without a second argument is interpreted as setting the variable to `on`, for control variables that accept that value, and is rejected for others. Also, control variables that accept the values `on` and `off` will also accept other common spellings of Boolean values, such as `true` and `false`.

The specially treated variables are:

## AUTOCOMMIT

When **on** (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a **BEGIN** or **START TRANSACTION** SQL command. When **off** or **unset**, SQL commands are not committed until you explicitly issue **COMMIT** or **END**. The autocommit-off mode works by issuing an implicit **BEGIN** for you, just before any command that is not already in a transaction block and is not itself a **BEGIN** or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as **VACUUM**).

### Note

In autocommit-off mode, you must explicitly abandon any failed transaction by entering **ABORT** or **ROLLBACK**. Also keep in mind that if you exit the session without committing, your work will be lost.

### Note

The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.

## COMP\_KEYWORD\_CASE

Determines which letter case to use when completing an SQL key word. If set to **lower** or **upper**, the completed word will be in lower or upper case, respectively. If set to **preserve-lower** or **preserve-upper** (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

## DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

## ECHO

If set to **all**, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch **-a**. If set to **queries**, `psql` prints each query to standard output as it is sent to the server. The switch to select this behavior is **-e**. If set to **errors**, then only failed queries are displayed on standard error output. The switch for this behavior is **-b**. If set to **none** (the default), then no queries are displayed.

## ECHO\_HIDDEN

When this variable is set to **on** and a backslash command queries the database, the query is first shown. This feature helps you to study PostgreSQL internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch **-E**.) If you set this variable to the value **noexec**, the queries are just shown but are not actually sent to the server and executed. The default value is **off**.

## ENCODING

The current client character set encoding. This is set every time you connect to a database (including program start-up), and when you change the encoding with `\encoding`, but it can be changed or unset.

**ERROR**

`true` if the last SQL query failed, `false` if it succeeded. See also `SQLSTATE`.

**FETCH\_COUNT**

If this variable is set to an integer value greater than zero, the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

**Tip**

Although you can use any output format with this feature, the default `aligned` format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

**HIDE\_TABLEAM**

If this variable is set to `true`, a table's access method details are not displayed. This is mainly useful for regression tests.

**HIDE\_TOAST\_COMPRESSION**

If this variable is set to `true`, column compression method details are not displayed. This is mainly useful for regression tests.

**HISTCONTROL**

If this variable is set to `ignore space`, lines which begin with a space are not entered into the history list. If set to a value of `ignore dups`, lines matching the previous history line are not entered. A value of `ignore both` combines the two options. If set to `none` (the default), all lines read in interactive mode are saved on the history list.

**Note**

This feature was shamelessly plagiarized from Bash.

**HISTFILE**

The file name that will be used to store the history list. If unset, the file name is taken from the `PSQL_HISTORY` environment variable. If that is not set either, the default is `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows. For example, putting:

```
\set HISTFILE ~/.psql_history-:DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

**Note**

This feature was shamelessly plagiarized from Bash.

## HISTSIZE

The maximum number of commands to store in the command history (default 500). If set to a negative value, no limit is applied.

### Note

This feature was shamelessly plagiarized from Bash.

## HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

## IGNOREEOF

If set to 1 or less, sending an EOF character (usually **Control+D**) to an interactive session of psql will terminate the application. If set to a larger numeric value, that many consecutive EOF characters must be typed to make an interactive session terminate. If the variable is set to a non-numeric value, it is interpreted as 10. The default is 0.

### Note

This feature was shamelessly plagiarized from Bash.

## LASTOID

The value of the last affected OID, as returned from an **INSERT** or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed. PostgreSQL servers since version 12 do not support OID system columns anymore, thus LASTOID will always be 0 following **INSERT** when targeting such servers.

## LAST\_ERROR\_MESSAGE

## LAST\_ERROR\_SQLSTATE

The primary error message and associated SQLSTATE code for the most recent failed query in the current psql session, or an empty string and 00000 if no error has occurred in the current session.

## ON\_ERROR\_ROLLBACK

When set to **on**, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to **interactive**, such errors are only ignored in interactive sessions, and not when reading script files. When set to **off** (the default), a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit **SAVEPOINT** for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

## ON\_ERROR\_STOP

By default, command processing continues after an error. When this variable is set to **on**, processing will instead stop immediately. In interactive mode, psql will return to the command prompt; otherwise, psql will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately.

If the top-level command string contained multiple SQL commands, processing will stop with the current command.

**PIPELINE\_COMMAND\_COUNT**

The number of commands queued in an ongoing pipeline.

**PIPELINE\_RESULT\_COUNT**

The number of commands of an ongoing pipeline that were followed by either a `\flushrequest` or a `\syncpipeline`, forcing the server to send the results. These results can be retrieved with `\getresults`.

**PIPELINE\_SYNC\_COUNT**

The number of sync messages queued in an ongoing pipeline.

**PORT**

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be changed or unset.

**PROMPT1****PROMPT2****PROMPT3**

These specify what the prompts psql issues should look like. See Prompting below.

**QUIET**

Setting this variable to `ON` is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

**ROW\_COUNT**

The number of rows returned or affected by the last SQL query, or 0 if the query failed or did not report a row count.

**SERVER\_VERSION\_NAME****SERVER\_VERSION\_NUM**

The server's version number as a string, for example `9.6.2`, `10.1` or `11beta1`, and in numeric form, for example `90602` or `100001`. These are set every time you connect to a database (including program start-up), but can be changed or unset.

**SERVICE**

The service name, if applicable.

**SHELL\_ERROR**

`true` if the last shell command failed, `false` if it succeeded. This applies to shell commands invoked via the `\!`, `\g`, `\o`, `\w`, and `\copy` meta-commands, as well as backquote (```) expansion. Note that for `\o`, this variable is updated when the output pipe is closed by the next `\o` command. See also `SHELL_EXIT_CODE`.

**SHELL\_EXIT\_CODE**

The exit status returned by the last shell command. 0–127 represent program exit codes, 128–255 indicate termination by a signal, and -1 indicates failure to launch a program or to collect its exit status. This applies to shell commands invoked via the `\!`, `\g`, `\o`, `\w`, and `\copy` meta-

commands, as well as backquote ( ``` ) expansion. Note that for `\O`, this variable is updated when the output pipe is closed by the next `\O` command. See also `SHELL_ERROR`.

#### `SHOW_ALL_RESULTS`

When this variable is set to `off`, only the last result of a combined query (`\;`) is shown instead of all of them. The default is `on`. The off behavior is for compatibility with older versions of psql.

#### `SHOW_CONTEXT`

This variable can be set to the values `never`, `errors`, or `always` to control whether `CONTEXT` fields are displayed in messages from the server. The default is `errors` (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when `VERBOSITY` is set to `terse` or `sqlstate`. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

#### `SINGLELINE`

Setting this variable to `on` is equivalent to the command line option `-S`.

#### `SINGLESTEP`

Setting this variable to `on` is equivalent to the command line option `-s`.

#### `SQLSTATE`

The error code (see Appendix A) associated with the last SQL query's failure, or `00000` if it succeeded.

#### `USER`

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be changed or unset.

#### `VERBOSITY`

This variable can be set to the values `default`, `verbose`, `terse`, or `sqlstate` to control the verbosity of error reports. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

#### `VERSION`

##### `VERSION_NAME`

##### `VERSION_NUM`

These variables are set at program start-up to reflect psql's version, respectively as a verbose string, a short string (e.g., `9.6.2`, `10.1`, or `11beta1`), and a number (e.g., `90602` or `100001`). They can be changed or unset.

#### `WATCH_INTERVAL`

This variable sets the default interval, in seconds, which `\watch` waits between executing the query. The default is 2 seconds. Specifying an interval in the command overrides this variable.

## SQL Interpolation

A key feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (`:`). For example,

```
testdb=> \set foo 'my_table'
```

```
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `:foo` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (: 'content');
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `: 'name'`, or `: "name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The `: {?name}` special syntax returns TRUE or FALSE depending on whether the variable exists or not, and is thus always substituted, unless the colon is backslash-escaped.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are PostgreSQL extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a psql extension.

## Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M

The full host name (with domain name) of the database server, or `[local]` if the connection is over a Unix domain socket, or `[local:/dir/name]`, if the Unix domain socket is not at the compiled in default location.

%m

The host name of the database server, truncated at the first dot, or [local] if the connection is over a Unix domain socket.

%>

The port number at which the database server is listening.

%n

The database session user name. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%S

The name of the service.

%/

The name of the current database.

%~

Like %/, but the output is ~ (tilde) if the database is your default database.

%#

If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%p

The process ID of the backend currently connected to.

%P

Pipeline status: off when not in a pipeline, on when in an ongoing pipeline or abort when in an aborted pipeline.

%R

In prompt 1 normally =, but @ if the session is in an inactive branch of a conditional block, or ^ if in single-line mode, or ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 %R is replaced by a character that depends on why psql expects more input: - if the command simply wasn't terminated yet, but \* if there is an unfinished / \* . . . \*/ comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or ( if there is an unmatched left parenthesis. In prompt 3 %R doesn't produce anything.

%x

Transaction status: an empty string when not in a transaction block, or \* when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%l

The line number inside the current statement, starting from 1.

%*digits*

The character with the indicated octal code is substituted.

`%:name:`

The value of the psql variable *name*. See Variables, above, for details.

`%`command``

The output of *command*, similar to ordinary “back-tick” substitution.

`%[ ... %]`

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `%)`. Multiple pairs of these can occur within the prompt. For example:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]n@/%R%[%033[0m%]## '
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

`%w`

Whitespace of the same width as the most recent output of `PROMPT1`. This can be used as a `PROMPT2` setting, so that multi-line statements are aligned with the first line, but there is no visible secondary prompt.

To insert a percent sign into your prompt, write `%%`. The default prompts are `'/%R%x%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

### Note

This feature was shamelessly plagiarized from tcsh.

## Command-Line Editing

psql uses the Readline or libedit library, if available, for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Type up-arrow or control-P to retrieve previous lines.

You can also use tab completion to fill in partially-typed keywords and SQL object names in many (by no means all) contexts. For example, at the start of a command, typing `ins` and pressing TAB will fill in `insert into`. Then, typing a few characters of a table or schema name and pressing TAB will fill in the unfinished name, or offer a menu of possible completions when there's more than one. (Depending on the library in use, you may need to press TAB more than once to get a menu.)

Tab completion for SQL object names requires sending queries to the server to find possible matches. In some contexts this can interfere with other operations. For example, after `BEGIN` it will be too late to issue `SET TRANSACTION ISOLATION LEVEL` if a tab-completion query is issued in between. If you do not want tab completion at all, you can turn it off permanently by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

The `-n` (`--no-readline`) command line option can also be useful to disable use of Readline for a single run of `psql`. This prevents tab completion, use or recording of command line history, and editing of multi-line commands. It is particularly useful when you need to copy-and-paste text that contains TAB characters.

## Environment

### COLUMNS

If `\pset columns` is zero, controls the width for the `wrapped` format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

### PGDATABASE

### PGHOST

### PGPORT

### PGUSER

Default connection parameters (see Section 32.15).

### PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

### PSQL\_EDITOR

### EDITOR

### VISUAL

Editor used by the `\e`, `\ef`, and `\ev` commands. These variables are examined in the order listed; the first that is set is used. If none of them is set, the default is to use `vi` on Unix systems or `notepad.exe` on Windows systems.

### PSQL\_EDITOR\_LINENUMBER\_ARG

When `\e`, `\ef`, or `\ev` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
```

```
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

### PSQL\_HISTORY

Alternative location for the command history file. Tilde (`~`) expansion is performed.

### PSQL\_PAGER

### PAGER

If a query's results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. Use of the pager can be disabled by setting `PSQL_PAGER` or `PAGER` to an empty string, or by adjusting the pager-related options of the `\pset` command. These variables are examined in the order listed; the first that is set is used. If neither of them is set, the default is to use `more` on most platforms, but `less` on Cygwin.

**PSQL\_WATCH\_PAGER**

When a query is executed repeatedly with the `\watch` command, a pager is not used by default. This behavior can be changed by setting `PSQL_WATCH_PAGER` to a pager command, on Unix systems. The `pspg` pager (not part of PostgreSQL but available in many open source software distributions) can display the output of `\watch` if started with the option `--stream`.

**PSQLRC**

Alternative location of the user's `.psqlrc` file. Tilde (`~`) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 32.15).

## Files

**`psqlrc` and `~/.psqlrc`**

Unless it is passed an `-X` option, `psql` attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc`. By default it is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. Typically this directory will be `../etc/` relative to the directory containing the PostgreSQL executables. The directory to look in can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows the personal startup file is instead named `%APPDATA%\postgresql\psqlrc.conf`. In either case, this default file path can be overridden by setting the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made `psql`-version-specific by appending a dash and the PostgreSQL major or minor release identifier to the file name, for example `~/.psqlrc-18` or `~/.psqlrc-18.4`. The most specific version-matching file will be read in preference to a non-version-specific file. These version suffixes are added after determining the file path as explained above.

**`.psql_history`**

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `HISTFILE` `psql` variable or the `PSQL_HISTORY` environment variable.

## Notes

- `psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with servers of versions back to 9.2, though not necessarily

with servers newer than psql itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use psql to connect to several servers of different major versions, it is recommended that you use the newest version of psql. Alternatively, you can keep around a copy of psql from each major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before PostgreSQL 9.6, the `-c` option implied `-X (-no-psqlrc)`; this is no longer the case.
- Before PostgreSQL 8.4, psql allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

## Notes for Windows Users

psql is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

## Examples

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (  
testdb(> first integer not null default 0,  
testdb(> second text)  
testdb-> ;  
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table  
          Table "public.my_table"  
Column | Type   | Collation | Nullable | Default  
-----+-----+-----+-----+-----  
first  | integer |           | not null | 0  
second | text    |           |          |
```

Now we change the prompt to something more interesting:

```
testdb=> \set PROMPT1 '%n@m %~%R%# '  
peter@localhost testdb=>
```

Let's assume you have filled the table with data and want to take a look at it:

```
peter@localhost testdb=> SELECT * FROM my_table;
```

```
first | second
-----+-----
      1 | one
      2 | two
      3 | three
      4 | four
(4 rows)
```

You can display tables in different ways by using the `\pset` command:

```
peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;
+-----+-----+
| first | second |
+-----+-----+
|      1 | one    |
|      2 | two    |
|      3 | three  |
|      4 | four   |
+-----+-----+
(4 rows)

peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
first second
-----
      1 one
      2 two
      3 three
      4 four
(4 rows)

peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format csv
Output format is csv.
peter@localhost testdb=> \pset tuples_only
Tuples only is on.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep '\t'
Field separator is "\t".
peter@localhost testdb=> SELECT second, first FROM my_table;
one      1
two      2
three    3
four     4
```

Alternatively, use the short commands:

```

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
-[ RECORD 1 ]-
first  | 1
second | one
-[ RECORD 2 ]-
first  | 2
second | two
-[ RECORD 3 ]-
first  | 3
second | three
-[ RECORD 4 ]-
first  | 4
second | four

```

Also, these output format options can be set for just one query by using \g:

```

peter@localhost testdb=> SELECT * FROM my_table
peter@localhost testdb-> \g (format=aligned tuples_only=off
    expanded=on)
-[ RECORD 1 ]-
first  | 1
second | one
-[ RECORD 2 ]-
first  | 2
second | two
-[ RECORD 3 ]-
first  | 3
second | three
-[ RECORD 4 ]-
first  | 4
second | four

```

Here is an example of using the \df command to find only functions with names matching int\*pl and whose second argument is of type bigint:

```

testdb=> \df int*pl * bigint
                List of functions
 Schema      | Name      | Result data type | Argument data types |
Type
-----+-----+-----+-----
+-----
pg_catalog | int28pl | bigint          | smallint, bigint    |
func
pg_catalog | int48pl | bigint          | integer, bigint     |
func
pg_catalog | int8pl  | bigint          | bigint, bigint      |
func
(3 rows)

```

Here, the + option is used to display additional information about one of these functions, and x is used to display the results in expanded mode:

```
testdb=> \df+x int*pl integer bigint
```

```
List of functions
```

```
-[ RECORD 1 ]-----+-----
Schema                | pg_catalog
Name                  | int48pl
Result data type      | bigint
Argument data types   | integer, bigint
Type                  | func
Volatility             | immutable
Parallel              | safe
Owner                 | postgres
Security              | invoker
Leakproof?            | no
Access privileges     |
Language              | internal
Internal name         | int48pl
Description           | implementation of + operator
```

When suitable, query results can be shown in a crosstab representation with the `\crosstabview` command:

```
testdb=> SELECT first, second, first > 2 AS gt2 FROM my_table;
```

```
first | second | gt2
-----+-----+-----
      1 | one    | f
      2 | two    | f
      3 | three  | t
      4 | four   | t
```

```
(4 rows)
```

```
testdb=> \crosstabview first second
```

```
first | one | two | three | four
-----+-----+-----+-----+-----
      1 | f   |     |       |
      2 |     | f   |       |
      3 |     |     | t     |
      4 |     |     |       | t
```

```
(4 rows)
```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.

```
testdb=> SELECT t1.first as "A", t2.first+100 AS "B",
```

```
       t1.first*(t2.first+100) as "AxB",
```

```
testdb-> row_number() over(order by t2.first) AS ord
```

```
testdb-> FROM my_table t1 CROSS JOIN my_table t2 ORDER BY 1 DESC
```

```
testdb-> \crosstabview "A" "B" "AxB" ord
```

```
A | 101 | 102 | 103 | 104
---+---+---+---+---
  4 | 404 | 408 | 412 | 416
  3 | 303 | 306 | 309 | 312
  2 | 202 | 204 | 206 | 208
  1 | 101 | 102 | 103 | 104
(4 rows)
```

---

# reindexdb

reindexdb — reindex a PostgreSQL database

## Synopsis

```
reindexdb [connection-option...] [option...] [ -S | --schema schema ] ... [ -t | --table table ] ... [ -i | --index index ] ... [ -s | --system ] [dbname | -a | --all ]
```

## Description

reindexdb is a utility for rebuilding indexes in a PostgreSQL database.

reindexdb is a wrapper around the SQL command REINDEX. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

## Options

reindexdb accepts the following command-line arguments:

-a  
--all

Reindex all databases.

--concurrently

Use the CONCURRENTLY option. See REINDEX, where all the caveats of this option are explained in detail.

[-d] *dbname*  
[--dbname=]*dbname*

Specifies the name of the database to be reindexed, when -a/--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e  
--echo

Echo the commands that reindexdb generates and sends to the server.

-i *index*  
--index=*index*

Recreate *index* only. Multiple indexes can be recreated by writing multiple -i switches.

-j *njobs*  
--jobs=*njobs*

Execute the reindex commands in parallel by running *njobs* commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

reindexdb will open *njobs* connections to the database, so make sure your max\_connections setting is high enough to accommodate all connections.

Note that this option is incompatible with the `--system` option.

`-q`  
`--quiet`

Do not display progress messages.

`-s`  
`--system`

Reindex database's system catalogs only.

`-S schema`  
`--schema=schema`

Reindex *schema* only. Multiple schemas can be reindexed by writing multiple `-S` switches.

`-t table`  
`--table=table`

Reindex *table* only. Multiple tables can be reindexed by writing multiple `-t` switches.

`--tablespace=tablespace`

Specifies the tablespace where indexes are rebuilt. (This name is processed as a double-quoted identifier.)

`-v`  
`--verbose`

Print detailed information during processing.

`-V`  
`--version`

Print the reindexdb version and exit.

`-?`  
`--help`

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--maintenance-db=dbname`

When the `-a/--all` is used, connect to this database to gather the list of databases to reindex. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `REINDEX` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table=foo --index=bar abcd
```

# vacuumdb

vacuumdb — garbage-collect and analyze a PostgreSQL database

## Synopsis

```
vacuumdb [connection-option...] [option...] [ -t | --table table [(column[,...])]] ...  
[ dbname | -a | --all ]
```

```
vacuumdb [connection-option...] [option...] [ -n | --schema schema ] ... [ dbname |  
-a | --all ]
```

```
vacuumdb [connection-option...] [option...] [ -N | --exclude-schema schema ] ... [ dbname |  
-a | --all ]
```

## Description

vacuumdb is a utility for cleaning a PostgreSQL database. vacuumdb will also generate internal statistics used by the PostgreSQL query optimizer.

vacuumdb is a wrapper around the SQL command `VACUUM`. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

## Options

vacuumdb accepts the following command-line arguments:

**-a**  
**--all**

Vacuum all databases.

**--buffer-usage-limit** *size*

Specifies the *Buffer Access Strategy* ring buffer size for a given invocation of vacuumdb. This size is used to calculate the number of shared buffers which will be reused as part of this strategy. See `VACUUM`.

**[-d]** *dbname*  
**[- -dbname=]***dbname*

Specifies the name of the database to be cleaned or analyzed, when **-a**/**--all** is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The *dbname* can be a connection string. If so, connection string parameters will override any conflicting command line options.

**--disable-page-skipping**

Disable skipping pages based on the contents of the visibility map.

**-e**  
**--echo**

Echo the commands that vacuumdb generates and sends to the server.

**-f**  
**--full**

Perform “full” vacuuming.

**-F**  
**--freeze**

Aggressively “freeze” tuples.

**--force-index-cleanup**

Always remove index entries pointing to dead tuples.

**-j *njobs***  
**--jobs=*njobs***

Execute the vacuum or analyze commands in parallel by running *njobs* commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

*vacuumdb* will open *njobs* connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Note that using this mode together with the **-f (FULL)** option might cause deadlock failures if certain system catalogs are processed in parallel.

**--min-mxid-age *mxid\_age***

Only execute the vacuum or analyze commands on tables with a multixact ID age of at least *mxid\_age*. This setting is useful for prioritizing tables to process to prevent multixact ID wrap-around (see Section 24.1.5.1).

For the purposes of this option, the multixact ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by *vacuumdb* will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

**--min-xid-age *xid\_age***

Only execute the vacuum or analyze commands on tables with a transaction ID age of at least *xid\_age*. This setting is useful for prioritizing tables to process to prevent transaction ID wrap-around (see Section 24.1.5).

For the purposes of this option, the transaction ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by *vacuumdb* will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

**--missing-stats-only**

Only analyze relations that are missing statistics for a column, index expression, or extended statistics object. When used with **--analyze-in-stages**, this option prevents *vacuumdb* from temporarily replacing existing statistics with ones generated with lower statistics targets, thus avoiding transiently worse query optimizer choices.

This option can only be used in conjunction with **--analyze-only** or **--analyze-in-stages**.

Note that **--missing-stats-only** requires `SELECT` privileges on `pg_statistic` and `pg_statistic_ext_data`, which are restricted to superusers by default.

**-n *schema***  
**--schema=*schema***

Clean or analyze all tables in *schema* only. Multiple schemas can be vacuumed by writing multiple **-n** switches.

**-N *schema***

**--exclude-schema=*schema***

Do not clean or analyze any tables in *schema*. Multiple schemas can be excluded by writing multiple -N switches.

**--no-index-cleanup**

Do not remove index entries pointing to dead tuples.

**--no-process-main**

Skip the main relation.

**--no-process-toast**

Skip the TOAST table associated with the table to vacuum, if any.

**--no-truncate**

Do not truncate empty pages at the end of the table.

**-P *parallel\_workers***

**--parallel=*parallel\_workers***

Specify the number of parallel workers for *parallel vacuum*. This allows the vacuum to leverage multiple CPUs to process indexes. See VACUUM.

**-q**

**--quiet**

Do not display progress messages.

**--skip-locked**

Skip relations that cannot be immediately locked for processing.

**-t *table* [ (*column* [, ...]) ]**

**--table=*table* [ (*column* [, ...]) ]**

Clean or analyze *table* only. Column names can be specified only in conjunction with the --analyze or --analyze-only options. Multiple tables can be vacuumed by writing multiple -t switches.

### Tip

If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

**-v**

**--verbose**

Print detailed information during processing.

**-V**

**--version**

Print the vacuumdb version and exit.

**-Z**  
**--analyze**

Also calculate statistics for use by the optimizer.

**-Z**  
**--analyze-only**

Only calculate statistics for use by the optimizer (no vacuum).

**--analyze-in-stages**

Only calculate statistics for use by the optimizer (no vacuum), like **--analyze-only**. Run three stages of analyze; the first stage uses the lowest possible statistics target (see `default_statistics_target`) to produce usable statistics faster, and subsequent stages build the full statistics.

This option is only useful to analyze a database that currently has no statistics or has wholly incorrect ones, such as if it is newly populated from a restored dump or by `pg_upgrade`. Be aware that running with this option in a database with existing statistics may cause the query optimizer choices to become transiently worse due to the low statistics targets of the early stages.

**-?**  
**--help**

Show help about vacuumdb command line arguments, and exit.

vacuumdb also accepts the following command-line arguments for connection parameters:

**-h *host***  
**--host=*host***

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

**-p *port***  
**--port=*port***

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

**-U *username***  
**--username=*username***

User name to connect as.

**-w**  
**--no-password**

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**-W**  
**--password**

Force vacuumdb to prompt for a password before connecting to a database.

This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing **-W** to avoid the extra connection attempt.

`--maintenance-db=dbname`

When the `-a/--all` is used, connect to this database to gather the list of databases to vacuum. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

## Diagnostics

In case of difficulty, see `VACUUM` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To clean the database `test`:

```
$ vacuumdb test
```

To clean and analyze for the optimizer a database named `bigdb`:

```
$ vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `xyzyz`, and analyze a single column `bar` of the table for the optimizer:

```
$ vacuumdb --analyze --verbose --table='foo(bar)' xyzyz
```

To clean all tables in the `foo` and `bar` schemas in a database named `xyzyz`:

```
$ vacuumdb --schema='foo' --schema='bar' xyzyz
```

# initdb

initdb — create a new PostgreSQL database cluster

## Synopsis

```
initdb [option...][ --pgdata | -D ] directory
```

## Description

`initdb` creates a new PostgreSQL *database cluster*.

Creating a database cluster consists of creating the *directories* in which the cluster data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the `postgres`, `template1`, and `template0` databases. The `postgres` database is a default database meant for use by users, utilities and third party applications. `template1` and `template0` are meant as source databases to be copied by later `CREATE DATABASE` commands. `template0` should never be modified, but you can add objects to `template1`, which by default will be copied into databases created later. See Section 22.3 for more details.

Although `initdb` will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use `chown` to assign ownership of that directory to the database user account, then `su` to become the database user to run `initdb`.

`initdb` must be run as the user that will own the server process, because the server needs to have access to the files and directories that `initdb` creates. Since the server cannot be run as root, you must not run `initdb` as root either. (It will in fact refuse to do so.)

For security reasons the new cluster created by `initdb` will only be accessible by the cluster owner by default. The `--allow-group-access` option allows any user in the same group as the cluster owner to read files in the cluster. This is useful for performing backups as a non-privileged user.

`initdb` initializes the database cluster's default locale and character set encoding. These can also be set separately for each database when it is created. `initdb` determines those settings for the template databases, which will serve as the default for all other databases.

By default, `initdb` uses the locale provider `libc` (see Section 23.1.4). The `libc` locale provider takes the locale settings from the environment, and determines the encoding from the locale settings.

To choose a different locale for the cluster, use the option `--locale`. There are also individual options `--lc-*` and `--icu-locale` (see below) to set values for the individual locale categories. Note that inconsistent settings for different locale categories can give nonsensical results, so this should be used with care.

Alternatively, `initdb` can use the ICU library to provide locale services by specifying `--locale-provider=icu`. The server must be built with ICU support. To choose the specific ICU locale ID to apply, use the option `--icu-locale`. Note that for implementation reasons and to support legacy code, `initdb` will still select and initialize `libc` locale settings when the ICU locale provider is used.

When `initdb` runs, it will print out the locale settings it has chosen. If you have complex requirements or specified multiple options, it is advisable to check that the result matches what was intended.

More details about locale settings can be found in Section 23.1.

To alter the default encoding, use the `--encoding`. More details can be found in Section 23.3.

## Options

`-A authmethod`

`--auth=authmethod`

This option specifies the default authentication method for local users used in `pg_hba.conf` (host and local lines). See Section 20.1 for an overview of valid values.

`initdb` will prepopulate `pg_hba.conf` entries using the specified authentication method for non-replication as well as replication connections.

Do not use `trust` unless you trust all local users on your system. `trust` is the default for ease of installation.

`--auth-host=authmethod`

This option specifies the authentication method for local users via TCP/IP connections used in `pg_hba.conf` (host lines).

`--auth-local=authmethod`

This option specifies the authentication method for local users via Unix-domain socket connections used in `pg_hba.conf` (local lines).

`-D directory`

`--pgdata=directory`

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the data directory later by the same variable.

`-E encoding`

`--encoding=encoding`

Selects the encoding of the template databases. This will also be the default encoding of any database you create later, unless you override it then. The character sets supported by the PostgreSQL server are described in Section 23.3.1.

By default, the template database encoding is derived from the locale. If `--no-locale` is specified (or equivalently, if the locale is `C` or `POSIX`), then the default is `UTF8` for the ICU provider and `SQL_ASCII` for the `libc` provider.

`-g`

`--allow-group-access`

Allows users in the same group as the cluster owner to read all cluster files created by `initdb`. This option is ignored on Windows as it does not support POSIX-style group permissions.

`--icu-locale=locale`

Specifies the ICU locale when the ICU provider is used. Locale support is described in Section 23.1.

`--icu-rules=rules`

Specifies additional collation rules to customize the behavior of the default collation. This is supported for ICU only.

-k

--data-checksums

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. This is enabled by default; use `--no-data-checksums` to disable checksums.

Enabling checksums might incur a small performance penalty. If set, checksums are calculated for all objects, in all databases. All checksum failures will be reported in the `pg_stat_database` view. See Section 28.2 for details.

--locale=*locale*

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in Section 23.1.

If `--locale-provider` is `builtin`, `--locale` or `--builtin-locale` must be specified and set to `C`, `C.UTF-8` or `PG_UNICODE_FAST`.

--lc-collate=*locale*

--lc-ctype=*locale*

--lc-messages=*locale*

--lc-monetary=*locale*

--lc-numeric=*locale*

--lc-time=*locale*

Like `--locale`, but only sets the locale in the specified category.

--no-locale

Equivalent to `--locale=C`.

--builtin-locale=*locale*

Specifies the locale name when the builtin provider is used. Locale support is described in Section 23.1.

--locale-provider={builtin|libc|icu}

This option sets the locale provider for databases created in the new cluster. It can be overridden in the `CREATE DATABASE` command when new databases are subsequently created. The default is `libc` (see Section 23.1.4).

--no-data-checksums

Do not enable data checksums.

--pwfile=*filename*

Makes `initdb` read the bootstrap superuser's password from a file. The first line of the file is taken as the password.

-T *config*

--text-search-config=*config*

Sets the default text search configuration. See `default_text_search_config` for further information.

-U *username*

--username=*username*

Sets the user name of the *bootstrap superuser*. This defaults to the name of the operating-system user running `initdb`.

**-w**  
**--pwprompt**

Makes `initdb` prompt for a password to give the bootstrap superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

**-X *directory***  
**--waldir=*directory***

This option specifies the directory where the write-ahead log should be stored.

**--wal-segsize=*size***

Set the *WAL segment size*, in megabytes. This is the size of each individual file in the WAL log. The default size is 16 megabytes. The value must be a power of 2 between 1 and 1024 (megabytes). This option can only be set during initialization, and cannot be changed later.

It may be useful to adjust this size to control the granularity of WAL log shipping or archiving. Also, in databases with a high volume of WAL, the sheer number of WAL files per directory can become a performance and management problem. Increasing the WAL file size will reduce the number of WAL files.

Other, less commonly used, options are also available:

**-c *name=value***  
**--set *name=value***

Forcibly set the server parameter *name* to *value* during `initdb`, and also install that setting in the generated `postgresql.conf` file, so that it will apply during future server runs. This option can be given more than once to set several parameters. It is primarily useful when the environment is such that the server will not start at all using the default parameters.

**-d**  
**--debug**

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

**--discard-caches**

Run the bootstrap backend with the `debug_discard_caches=1` option. This takes a very long time and is only of use for deep debugging.

**-L *directory***

Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

**-n**  
**--no-clean**

By default, when `initdb` determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

**-N**  
**--no-sync**

By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can

leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

#### `--no-sync-data-files`

By default, `initdb` safely writes all database files to disk. This option instructs `initdb` to skip synchronizing all files in the individual database directories, the database directories themselves, and the tablespace directories, i.e., everything in the `base` subdirectory and any other tablespace directories. Other files, such as those in `pg_wal` and `pg_xact`, will still be synchronized unless the `--no-sync` option is also specified.

Note that if `--no-sync-data-files` is used in conjunction with `--sync-method=syncfs`, some or all of the aforementioned files and directories will be synchronized because `syncfs` processes entire file systems.

This option is primarily intended for internal use by tools that separately ensure the skipped files are synchronized to disk.

#### `--no-instructions`

By default, `initdb` will write instructions for how to start the cluster at the end of its output. This option causes those instructions to be left out. This is primarily intended for use by tools that wrap `initdb` in platform-specific behavior, where those instructions are likely to be incorrect.

#### `-s`

#### `--show`

Show internal settings and exit, without doing anything else. This can be used to debug the `initdb` installation.

#### `--sync-method=method`

When set to `fsync`, which is the default, `initdb` will recursively open and synchronize all files in the data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the data directory, the WAL files, and each tablespace. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

#### `-S`

#### `--sync-only`

Safely write all database files to disk and exit. This does not perform any of the normal `initdb` operations. Generally, this option is useful for ensuring reliable recovery after changing `fsync` from `off` to `on`.

Other options:

#### `-V`

#### `--version`

Print the `initdb` version and exit.

#### `-?`

#### `--help`

Show help about `initdb` command line arguments, and exit.

## Environment

### PGDATA

Specifies the directory where the database cluster is to be stored; can be overridden using the `-D` option.

### PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

### TZ

Specifies the default time zone of the created database cluster. The value should be a full time zone name (see Section 8.5.3).

## Notes

`initdb` can also be invoked via `pg_ctl initdb`.

## See Also

`pg_ctl`, `postgres`, Section 20.1

---

# pg\_archivecleanup

pg\_archivecleanup — clean up PostgreSQL WAL archive files

## Synopsis

pg\_archivecleanup [*option...*] *archive location oldestkeptwalfile*

## Description

pg\_archivecleanup is designed to be used as an `archive_cleanup_command` to clean up WAL file archives when running as a standby server (see Section 26.2). pg\_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg\_archivecleanup, put this into its `postgresql.conf` configuration file:

```
archive_cleanup_command = 'pg_archivecleanup archive location %r'
```

where *archive location* is the directory from which WAL segment files should be removed.

When used within `archive_cleanup_command`, all WAL files logically preceding the value of the `%r` argument will be removed from *archive location*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archive location* is a transient staging area for this particular standby server, but *not* when the *archive location* is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the *oldestkeptwalfile* will be removed from *archive location*. In this mode, if you specify a `.partial` or `.backup` file name, then only the file prefix will be used as the *oldestkeptwalfile*. This treatment of `.backup` file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name `0000000100000003700000010`:

```
pg_archivecleanup -d archive
0000000100000003700000010.00000020.backup
```

```
pg_archivecleanup: keep WAL file
"archive/0000000100000003700000010" and later
pg_archivecleanup: removing file
"archive/000000010000000370000000F"
pg_archivecleanup: removing file
"archive/000000010000000370000000E"
```

pg\_archivecleanup assumes that *archive location* is a directory readable and writable by the server-owning user.

## Options

pg\_archivecleanup accepts the following command-line arguments:

```
-b
--clean-backup-history
```

Remove backup history files as well. See Section 25.3.2 for details about backup history files.

-d  
--debug

Print lots of debug logging output on `stderr`.

-n  
--dry-run

Print the names of the files that would have been removed on `stdout` (performs a dry run).

-V  
--version

Print the `pg_archivecleanup` version and exit.

-x *extension*  
--strip-extension=*extension*

Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: -x `.gz`.

-?  
--help

Show help about `pg_archivecleanup` command line arguments, and exit.

## Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

`pg_archivecleanup` is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

`pg_archivecleanup` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

## Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/  
archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

---

# pg\_checksums

pg\_checksums — enable, disable or check data checksums in a PostgreSQL database cluster

## Synopsis

```
pg_checksums [option...] [[ -D | --pgdata ]datadir]
```

## Description

pg\_checksums checks, enables or disables data checksums in a PostgreSQL cluster. The server must be shut down cleanly before running pg\_checksums. When verifying checksums, the exit status is zero if there are no checksum errors, and nonzero if at least one checksum failure is detected. When enabling or disabling checksums, the exit status is nonzero if the operation failed.

When verifying checksums, every file in the cluster is scanned. When enabling checksums, each relation file block with a changed checksum is rewritten in-place. Disabling checksums only updates the file `pg_control`.

## Options

The following command-line options are available:

`-D directory`  
`--pgdata=directory`

Specifies the directory where the database cluster is stored.

`-c`  
`--check`

Checks checksums. This is the default mode if nothing else is specified.

`-d`  
`--disable`

Disables checksums.

`-e`  
`--enable`

Enables checksums.

`-f filenode`  
`--filenode=filenode`

Only validate checksums in the relation with filenode *filenode*.

`-N`  
`--no-sync`

By default, pg\_checksums will wait for all files to be written safely to disk. This option causes pg\_checksums to return without waiting, which is faster, but means that a subsequent operating system crash can leave the updated data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation. This option has no effect when using `--check`.

**-P**

**--progress**

Enable progress reporting. Turning this on will deliver a progress report while checking or enabling checksums.

**--sync-method=method**

When set to `fsync`, which is the default, `pg_checksums` will recursively open and synchronize all files in the data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the data directory, the WAL files, and each tablespace. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

**-v**

**--verbose**

Enable verbose output. Lists all checked files.

**-V**

**--version**

Print the `pg_checksums` version and exit.

**-?**

**--help**

Show help about `pg_checksums` command line arguments, and exit.

## Environment

**PGDATA**

Specifies the directory where the database cluster is stored; can be overridden using the `-D` option.

**PG\_COLOR**

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

Enabling checksums in a large cluster can potentially take a long time. During this operation, the cluster or other programs that write to the data directory must not be started or else data loss may occur.

When using a replication setup with tools which perform direct copies of relation file blocks (for example `pg_rewind`), enabling or disabling checksums can lead to page corruptions in the shape of incorrect checksums if the operation is not done consistently across all nodes. When enabling or disabling checksums in a replication setup, it is thus recommended to stop all the clusters before switching them all consistently. Destroying all standbys, performing the operation on the primary and finally recreating the standbys from scratch is also safe.

If `pg_checksums` is aborted or killed while enabling or disabling checksums, the cluster's data checksum configuration remains unchanged, and `pg_checksums` can be re-run to perform the same operation.

---

# pg\_controldata

pg\_controldata — display control information of a PostgreSQL database cluster

## Synopsis

```
pg_controldata [option] [[ -D | --pgdata ]datadir]
```

## Description

pg\_controldata prints information initialized during `initdb`, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable `PGDATA`. This utility supports the options `-V` and `--version`, which print the pg\_controldata version and exit. It also supports options `-?` and `--help`, which output the supported arguments.

## Environment

**PGDATA**

Default data directory location

**PG\_COLOR**

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

---

# pg\_createsubscriber

pg\_createsubscriber — convert a physical replica into a new logical replica

## Synopsis

```
pg_createsubscriber [option...] { -d | --database }dbname { -D | --pgdata }datadir { -P | --publisher-server }connstr
```

## Description

pg\_createsubscriber creates a new logical replica from a physical standby server. All tables in the specified database are included in the logical replication setup. A pair of publication and subscription objects are created for each database. It must be run at the target server.

After a successful run, the state of the target server is analogous to a fresh logical replication setup. The main difference between the logical replication setup and pg\_createsubscriber is how the data synchronization is done. pg\_createsubscriber does not copy the initial table data. It does only the synchronization phase, which ensures each table is brought up to a synchronized state.

pg\_createsubscriber targets large database systems because in logical replication setup, most of the time is spent doing the initial data copy. Furthermore, a side effect of this long time spent synchronizing data is usually a large amount of changes to be applied (that were produced during the initial data copy), which increases even more the time when the logical replica will be available. For smaller databases, it is recommended to set up logical replication with initial data synchronization. For details, see the CREATE SUBSCRIPTION copy\_data option.

## Options

pg\_createsubscriber accepts the following command-line arguments:

**-a**  
**--all**

Create one subscription per database on the target server. Exceptions are template databases and databases that don't allow connections. To discover the list of all databases, connect to the source server using the database name specified in the --publisher-server connection string, or if not specified, the postgres database will be used, or if that does not exist, template1 will be used. Automatically generated names for subscriptions, publications, and replication slots are used when this option is specified. This option cannot be used along with --database, --publication, --replication-slot, or --subscription.

**-d** *dbname*  
**--database=***dbname*

The name of the database in which to create a subscription. Multiple databases can be selected by writing multiple -d switches. This option cannot be used together with -a. If -d option is not provided, the database name will be obtained from -P option. If the database name is not specified in either the -d option, or the -P option, and -a option is not specified, an error will be reported.

**-D** *directory*  
**--pgdata=***directory*

The target directory that contains a cluster directory from a physical replica.

**-n**  
**--dry-run**

Do everything except actually modifying the target directory.

**-p *port***  
**--subscriber-port=*port***

The port number on which the target server is listening for connections. Defaults to running the target server on port 50432 to avoid unintended client connections.

**-P *connstr***  
**--publisher-server=*connstr***

The connection string to the publisher. For details see Section 32.1.1.

**-s *dir***  
**--socketdir=*dir***

The directory to use for postmaster sockets on target server. The default is current directory.

**-t *seconds***  
**--recovery-timeout=*seconds***

The maximum number of seconds to wait for recovery to end. Setting to 0 disables. The default is 0.

**-T**  
**--enable-two-phase**

Enables `two_phase` commit for the subscription. When multiple databases are specified, this option applies uniformly to all subscriptions created on those databases. The default is `false`.

**-U *username***  
**--subscriber-username=*username***

The user name to connect as on target server. Defaults to the current operating system user name.

**-v**  
**--verbose**

Enables verbose mode. This will cause `pg_createsubscriber` to output progress messages and detailed information about each step to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

**--clean=*objtype***

Drop all objects of the specified type from specified databases on the target server.

- **publications**: The `FOR ALL TABLES` publications established for this subscriber are always dropped; specifying this object type causes all other publications replicated from the source server to be dropped as well.

The objects selected to be dropped are individually logged, including during a `--dry-run`. There is no opportunity to affect or stop the dropping of the selected objects, so consider taking a backup of them using `pg_dump`.

**--config-file=*filename***

Use the specified main server configuration file for the target data directory. `pg_createsubscriber` internally uses the `pg_ctl` command to start and stop the target server. It allows you to specify the actual `postgresql.conf` configuration file if it is stored outside the data directory.

**--publication=*name***

The publication name to set up the logical replication. Multiple publications can be specified by writing multiple **--publication** switches. The number of publication names must match the number of specified databases, otherwise an error is reported. The order of the multiple publication name switches must match the order of database switches. If this option is not specified, a generated name is assigned to the publication name. This option cannot be used together with **--all**.

**--replication-slot=*name***

The replication slot name to set up the logical replication. Multiple replication slots can be specified by writing multiple **--replication-slot** switches. The number of replication slot names must match the number of specified databases, otherwise an error is reported. The order of the multiple replication slot name switches must match the order of database switches. If this option is not specified, the subscription name is assigned to the replication slot name. This option cannot be used together with **--all**.

**--subscription=*name***

The subscription name to set up the logical replication. Multiple subscriptions can be specified by writing multiple **--subscription** switches. The number of subscription names must match the number of specified databases, otherwise an error is reported. The order of the multiple subscription name switches must match the order of database switches. If this option is not specified, a generated name is assigned to the subscription name. This option cannot be used together with **--all**.

**-V**

**--version**

Print the `pg_createsubscriber` version and exit.

**-?**

**--help**

Show help about `pg_createsubscriber` command line arguments, and exit.

## Notes

### Prerequisites

There are some prerequisites for `pg_createsubscriber` to convert the target server into a logical replica. If these are not met, an error will be reported. The source and target servers must have the same major version as the `pg_createsubscriber`. The given target data directory must have the same system identifier as the source data directory. The given database user for the target data directory must have privileges for creating subscriptions and using `pg_replication_origin_advance()`.

The target server must be used as a physical standby. The target server must have `max_active_replication_origins` and `max_logical_replication_workers` configured to a value greater than or equal to the number of specified databases. The target server must have `max_worker_processes` configured to a value greater than the number of specified databases. The target server must accept local connections. If you are planning to use the **--enable-two-phase** switch then you will also need to set the `max_prepared_transactions` appropriately.

The source server must accept connections from the target server. The source server must not be in recovery. The source server must have `wal_level` as `logical`. The source server must have `max_replication_slots` configured to a value greater than or equal to the number of specified databases plus existing replication slots. The source server must have `max_wal_senders` configured to a value greater than or equal to the number of specified databases and existing WAL sender processes.

## Warnings

If `pg_createsubscriber` fails after the target server was promoted, then the data directory is likely not in a state that can be recovered. In such case, creating a new standby server is recommended.

`pg_createsubscriber` usually starts the target server with different connection settings during transformation. Hence, connections to the target server should fail.

Since DDL commands are not replicated by logical replication, avoid executing DDL commands that change the database schema while running `pg_createsubscriber`. If the target server has already been converted to logical replica, the DDL commands might not be replicated, which might cause an error.

If `pg_createsubscriber` fails while processing, objects (publications, replication slots) created on the source server are removed. The removal might fail if the target server cannot connect to the source server. In such a case, a warning message will inform the objects left. If the target server is running, it will be stopped.

If the replication is using `primary_slot_name`, it will be removed from the source server after the logical replication setup.

If the target server is a synchronous replica, transaction commits on the primary might wait for replication while running `pg_createsubscriber`.

Unless the `--enable-two-phase` switch is specified, `pg_createsubscriber` sets up logical replication with two-phase commit disabled. This means that any prepared transactions will be replicated at the time of `COMMIT PREPARED`, without advance preparation. Once setup is complete, you can manually drop and re-create the subscription(s) with the `two_phase` option enabled.

`pg_createsubscriber` changes the system identifier using `pg_resetwal`. It would avoid situations in which the target server might use WAL files from the source server. If the target server has a standby, replication will break and a fresh standby should be created.

Replication failures can occur if required WAL files are missing. To prevent this, the source server must set `max_slot_wal_keep_size` to `-1` to ensure that required WAL files are not prematurely removed.

## How It Works

The basic idea is to have a replication start point from the source server and set up a logical replication to start from this point:

1. Start the target server with the specified command-line options. If the target server is already running, `pg_createsubscriber` will terminate with an error.
2. Check if the target server can be converted. There are also a few checks on the source server. If any of the prerequisites are not met, `pg_createsubscriber` will terminate with an error.
3. Create a publication and replication slot for each specified database on the source server. Each publication is created using `FOR ALL TABLES`. If the `--publication` option is not specified, the publication has the following name pattern: `"pg_createsubscriber_%u_%x"` (parameter: database *oid*, random *int*). If the `--replication-slot` option is not specified, the replication slot has the following name pattern: `"pg_createsubscriber_%u_%x"` (parameters: database *oid*, random *int*). These replication slots will be used by the subscriptions in a future step. The last replication slot LSN is used as a stopping point in the `recovery_target_lsn` parameter and by the subscriptions as a replication start point. It guarantees that no transaction will be lost.
4. Write recovery parameters into the target data directory and restart the target server. It specifies an LSN (`recovery_target_lsn`) of the write-ahead log location up to which recovery will proceed. It also specifies `promote` as the action that the server should take once the recovery target is

reached. Additional recovery parameters are added to avoid unexpected behavior during the recovery process such as end of the recovery as soon as a consistent state is reached (WAL should be applied until the replication start location) and multiple recovery targets that can cause a failure. This step finishes once the server ends standby mode and is accepting read-write transactions. If `--recovery-timeout` option is set, `pg_createsubscriber` terminates if recovery does not end until the given number of seconds.

5. Create a subscription for each specified database on the target server. If the `--subscription` option is not specified, the subscription has the following name pattern: “`pg_createsubscriber_%u_%x`” (parameters: database *oid*, random *int*). It does not copy existing data from the source server. It does not create a replication slot. Instead, it uses the replication slot that was created in a previous step. The subscription is created but it is not enabled yet. The reason is the replication progress must be set to the replication start point before starting the replication.
6. Drop publications on the target server that were replicated because they were created before the replication start location. It has no use on the subscriber.
7. Set the replication progress to the replication start point for each subscription. When the target server starts the recovery process, it catches up to the replication start point. This is the exact LSN to be used as a initial replication location for each subscription. The replication origin name is obtained since the subscription was created. The replication origin name and the replication start point are used in `pg_replication_origin_advance()` to set up the initial replication location.
8. Enable the subscription for each specified database on the target server. The subscription starts applying transactions from the replication start point.
9. If the standby server was using `primary_slot_name`, it has no use from now on so drop it.
10. If the standby server contains failover replication slots, they cannot be synchronized anymore, so drop them.
11. Update the system identifier on the target server. The `pg_resetwal` is run to modify the system identifier. The target server is stopped as a `pg_resetwal` requirement.

## Examples

To create a logical replica for databases `hr` and `finance` from a physical replica at `foo`:

```
$ pg_createsubscriber -D /usr/local/pgsql/data -P "host=foo" -d hr  
-d finance
```

pg_ctl logrotate [-D datadir] [-s]  
  
pg_ctl kill signal_name process_id  
  
On Microsoft Windows, also:  
  
pg_ctl register [-D datadir] [-N servicename] [-U username] [-P password] [-S  
a[uto] | d[emand] ] [-e source] [-W] [-t seconds] [-s] [-o options]  
  
pg_ctl unregister [-N servicename]
```

## Description

pg\_ctl is a utility for initializing a PostgreSQL database cluster, starting, stopping, or restarting the PostgreSQL database server (postgres), or displaying the status of a running server. Although the server can be started manually, pg\_ctl encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The `init` or `initdb` mode creates a new PostgreSQL database cluster, that is, a collection of databases that will be managed by a single server instance. This mode invokes the `initdb` command. See `initdb` for details.

`start` mode launches a new server. The server is started in the background, and its standard input is attached to `/dev/null` (or `nul` on Windows). On Unix-like systems, by default, the server's standard output and standard error are sent to pg\_ctl's standard output (not standard error). The standard output of pg\_ctl should then be redirected to a file or piped to another process such as a log rotating program like `rotatelog`s; otherwise `postgres` will write its output to the controlling terminal (from the background) and will not leave the shell's process group. On Windows, by default the server's standard output and standard error are sent to the terminal. These default behaviors can be changed by using `-l` to append the server's output to a log file. Use of either `-l` or output redirection is recommended.

`stop` mode shuts down the server that is running in the specified data directory. Three different shutdown methods can be selected with the `-m` option. “Smart” mode disallows new connections, then waits for all existing clients to disconnect. If the server is in hot standby, recovery and streaming repli-

cation will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This choice will lead to a crash-recovery cycle during the next server start.

**restart** mode effectively executes a stop followed by a start. This allows changing the **postgres** command-line options, or changing configuration-file options that cannot be changed without restarting the server. If relative paths were used on the command line during server start, **restart** might fail unless **pg\_ctl** is executed in the same current directory as it was during server start.

**reload** mode simply sends the **postgres** server process a **SIGHUP** signal, causing it to reread its configuration files (**postgresql.conf**, **pg\_hba.conf**, etc.). This allows changing configuration-file options that do not require a full server restart to take effect.

**status** mode checks whether a server is running in the specified data directory. If it is, the server's PID and the command line options that were used to invoke it are displayed. If the server is not running, **pg\_ctl** returns an exit status of 3. If an accessible data directory is not specified, **pg\_ctl** returns an exit status of 4.

**promote** mode commands the standby server that is running in the specified data directory to end standby mode and begin read-write operations.

**logrotate** mode rotates the server log file. For details on how to use this mode with external log rotation tools, see Section 24.3.

**kill** mode sends a signal to a specified process. This is primarily valuable on Microsoft Windows which does not have a built-in kill command. Use **--help** to see a list of supported signal names.

**register** mode registers the PostgreSQL server as a system service on Microsoft Windows. The **-S** option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

**unregister** mode unregisters a system service on Microsoft Windows. This undoes the effects of the **register** command.

## Options

**-c**  
**--core-files**

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

**-D *datadir***  
**--pgdata=*datadir***

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable **PGDATA** is used.

**-l *filename***  
**--log=*filename***

Append the server log output to *filename*. If the file does not exist, it is created. By default, only the cluster owner can access the log file. If group access is enabled in the cluster, users in the same group as the cluster owner can also read it.

**-m *mode***  
**--mode=*mode***

Specifies the shutdown mode. *mode* can be **smart**, **fast**, or **immediate**, or the first letter of one of these three. If this option is omitted, **fast** is the default.

**-o *options***  
**--options=*options***

Specifies options to be passed directly to the `postgres` command. `-o` can be specified multiple times, with all the given options being passed through.

The *options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

**-o *initdb-options***  
**--options=*initdb-options***

Specifies options to be passed directly to the `initdb` command. `-o` can be specified multiple times, with all the given options being passed through.

The *initdb-options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

**-p *path***

Specifies the location of the `postgres` executable. By default the `postgres` executable is taken from the same directory as `pg_ctl`, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the `postgres` executable was not found.

In `init` mode, this option analogously specifies the location of the `initdb` executable.

**-s**  
**--silent**

Print only errors, no informational messages.

**-t *seconds***  
**--timeout=*seconds***

Specifies the maximum number of seconds to wait when waiting for an operation to complete (see option `-w`). Defaults to the value of the `PGCTLTIMEOUT` environment variable or, if not set, to 60 seconds.

**-V**  
**--version**

Print the `pg_ctl` version and exit.

**-w**  
**--wait**

Wait for the operation to complete. This is supported for the modes `start`, `stop`, `restart`, `promote`, and `register`, and is the default for those modes.

When waiting, `pg_ctl` repeatedly checks the server's PID file, sleeping for a short amount of time between checks. Startup is considered complete when the PID file indicates that the server is ready to accept connections. Shutdown is considered complete when the server removes the PID file. `pg_ctl` returns an exit code based on the success of the startup or shutdown.

If the operation does not complete within the timeout (see option `-t`), then `pg_ctl` exits with a nonzero exit status. But note that the operation might continue in the background and eventually succeed.

**-W**  
**--no-wait**

Do not wait for the operation to complete. This is the opposite of the option `-w`.

If waiting is disabled, the requested action is triggered, but there is no feedback about its success. In that case, the server log file or an external monitoring system would have to be used to check the progress and success of the operation.

In prior releases of PostgreSQL, this was the default except for the `stop` mode.

-?  
--help

Show help about `pg_ctl` command line arguments, and exit.

If an option is specified that is valid, but not relevant to the selected operating mode, `pg_ctl` ignores it.

## Options for Windows

-e *source*

Name of the event source for `pg_ctl` to use for logging to the event log when running as a Windows service. The default is `PostgreSQL`. Note that this only controls messages sent from `pg_ctl` itself; once started, the server will use the event source specified by its `event_source` parameter. Should the server fail very early in startup, before that parameter has been set, it might also log using the default event source name `PostgreSQL`.

-N *servicename*

Name of the system service to register. This name will be used as both the service name and the display name. The default is `PostgreSQL`.

-P *password*

Password for the user to run the service as.

-S *start-type*

Start type of the system service. *start-type* can be `auto`, or `demand`, or the first letter of one of these two. If this option is omitted, `auto` is the default.

-U *username*

User name for the user to run the service as. For domain users, use the format `DOMAIN\user-name`.

## Environment

PGCTLTIMEOUT

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

PGDATA

Default data directory location.

Most `pg_ctl` modes require knowing the data directory location; therefore, the `-D` option is required unless `PGDATA` is set.

For additional variables that affect the server, see `postgres`.

## Files

`postmaster.pid`

`pg_ctl` examines this file in the data directory to determine whether the server is currently running.

postmaster.opts

If this file exists in the data directory, `pg_ctl` (in `restart` mode) will pass the contents of the file as options to postgres, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

## Examples

### Starting the Server

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

### Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over *how* the server shuts down:

```
$ pg_ctl stop -m smart
```

### Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that by default, `pg_ctl` saves and reuses the command line options that were passed to the previously-running instance. To restart the server using the same options as before, use:

```
$ pg_ctl restart
```

But if `-o` is specified, that replaces any previous options. To restart using port 5433, disabling `fsync` upon restart:

```
$ pg_ctl -o "-F -p 5433" restart
```

### Showing the Server Status

Here is sample status output from `pg_ctl`:

```
$ pg_ctl status
```

```
pg_ctl: server is running (PID: 13718)  
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p"  
"5433" "-B" "128"
```

The second line is the command that would be invoked in restart mode.

# pg\_resetwal

`pg_resetwal` — reset the write-ahead log and other control information of a PostgreSQL database cluster

## Synopsis

```
pg_resetwal [-f | --force] [-n | --dry-run] [option...] [-D | --pgdata] datadir
```

## Description

`pg_resetwal` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

Some options, such as `--wal-segsize` (see below), can also be used to modify certain global settings of a database cluster without the need to rerun `initdb`. This can be done safely on an otherwise sound database cluster, if none of the dangerous modes mentioned below are used.

If `pg_resetwal` is used on a data directory where the server has been cleanly shut down and the control file is sound, then it will have no effect on the contents of the database system, except that no longer used WAL files are cleared away. Any other use is potentially dangerous and must be done with great care. `pg_resetwal` will require the `-f` (force) option to be specified before working on a data directory in an unclean shutdown state or with a corrupted control file.

After running this command on a data directory with corrupted WAL or a corrupted control file, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and restore. After restore, check for inconsistencies and repair as needed.

If `pg_resetwal` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting location fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and restore is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory.

## Options

```
datadir  
-D datadir  
--pgdata=datadir
```

Specifies the location of the database directory. For safety reasons, you must specify the data directory on the command line. `pg_resetwal` does not use the environment variable `PGDATA`.

```
-f  
--force
```

Force `pg_resetwal` to proceed even in situations where it could be dangerous, as explained above. Specifically, this option is required to proceed if the server had not been cleanly shut down or if `pg_resetwal` cannot determine valid data for `pg_control`.

`-n`  
`--dry-run`

The `-n/--dry-run` option instructs `pg_resetwal` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetwal` to proceed for real.

`-V`  
`--version`

Display version information, then exit.

`-?`  
`--help`

Show help, then exit.

The following options are only needed when `pg_resetwal` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix `0x`. Note that these instructions only apply with the standard block size of 8 kB.

`-c xid,xid`  
`--commit-timestamp-ids=xid,xid`

Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

`-e xid_epoch`  
`--epoch=xid_epoch`

Manually set the next transaction ID's epoch.

The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetwal`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

`-l walfile`  
`--next-wal-file=walfile`

Manually set the WAL starting location by specifying the name of the next WAL segment file.

The name of next WAL segment file should be larger than any WAL segment file name currently existing in the directory `pg_wal` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `00000000100000003200000004A` is the largest entry in `pg_wal`, use `-l 00000000100000003200000004B` or higher.

Note that when using nondefault WAL segment sizes, the numbers in the WAL file names are different from the LSNs that are reported by system functions and system views. This option takes a WAL file name, not an LSN.

**Note**

`pg_resetwal` itself looks at the files in `pg_wal` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_wal`, such as entries in an offline archive; or if the contents of `pg_wal` have been lost entirely.

```
-m mxid,mxid  
--multixact-ids=mxid,mxid
```

Manually set the next and oldest multitransaction ID.

A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536 (0x10000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

```
-o oid  
--next-oid=oid
```

Manually set the next OID.

There is no comparably easy way to determine a next OID that's beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

```
-O mxoff  
--multixact-offset=mxoff
```

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352 (0xCC80). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

```
-u xid  
--oldest-transaction-id=xid
```

Manually set the oldest unfrozen transaction ID.

A safe value can be determined by looking for the numerically smallest file name in the directory `pg_xact` under the data directory and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0007` is the smallest entry in `pg_xact`, `-u 0x700000` will work (five trailing zeroes provide the proper multiplier).

```
-x xid  
--next-transaction-id=xid
```

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_xact` under the data directory, adding one, and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0011` is the largest entry in `pg_xact`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

`--char-signedness=option`

Manually set the default char signedness. Possible values are `signed` and `unsigned`.

For a database cluster that `pg_upgrade` upgraded from a PostgreSQL version before 18, the safe value would be the default `char` signedness of the platform that ran the cluster before that upgrade. For all other clusters, `signed` would be the safe value. However, this option is exclusively for use with `pg_upgrade` and should not normally be used manually.

`--wal-segsize=wal_segment_size`

Set the new WAL segment size, in megabytes. The value must be set to a power of 2 between 1 and 1024 (megabytes). See the same option of `initdb` for more information.

This option can also be used to change the WAL segment size of an existing database cluster, avoiding the need to `re-initdb`.

### Note

While `pg_resetwal` will set the WAL starting address beyond the latest existing WAL segment file, some segment size changes can cause previous WAL file names to be reused. It is recommended to use `-l` together with this option to manually set the WAL starting address if WAL file name overlap will cause problems with your archiving strategy.

## Environment

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

This command must not be used when the server is running. `pg_resetwal` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetwal` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetwal` works only with servers of the same major version.

# pg\_rewind

`pg_rewind` — synchronize a PostgreSQL data directory with another data directory that was forked from it

## Synopsis

```
pg_rewind [option...] { -D | --target-pgdata } directory { --source-pgdata=directory | --source-server=connstr }
```

## Description

`pg_rewind` is a tool for synchronizing a PostgreSQL cluster with another copy of the same cluster, after the clusters' timelines have diverged. A typical scenario is to bring an old primary server back online after failover as a standby that follows the new primary.

After a successful rewind, the state of the target data directory is analogous to a base backup of the source data directory. Unlike taking a new base backup or using a tool like `rsync`, `pg_rewind` does not require comparing or copying unchanged relation blocks in the cluster. Only changed blocks from existing relation files are copied; all other files, including new relation files, configuration files, and WAL segments, are copied in full. As such the rewind operation is significantly faster than other approaches when the database is large and only a small fraction of blocks differ between the clusters.

`pg_rewind` examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster's `pg_wal` directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, its old WAL files might no longer be present. In this case, you can manually copy them from the WAL archive to the `pg_wal` directory, or run `pg_rewind` with the `-C` option to automatically retrieve them from the WAL archive. The use of `pg_rewind` is not limited to failover, e.g., a standby server can be promoted, run some write transactions, and then rewound to become a standby again.

After running `pg_rewind`, WAL replay needs to complete for the data directory to be in a consistent state. When the target server is started again it will enter archive recovery and replay all WAL generated in the source server from the last checkpoint before the point of divergence. If some of the WAL was no longer available in the source server when `pg_rewind` was run, and therefore could not be copied by the `pg_rewind` session, it must be made available when the target server is started. This can be done by creating a `recovery.signal` file in the target data directory and by configuring a suitable `restore_command` in `postgresql.conf`.

`pg_rewind` requires that the target server either has the `wal_log_hints` option enabled in `postgresql.conf` or data checksums enabled when the cluster was initialized with `initdb` (the default). `full_page_writes` must also be set to `on`, but is enabled by default.

### Warning: Failures While Rewinding

If `pg_rewind` fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

As `pg_rewind` copies configuration files entirely from the source, it may be required to correct the configuration used for recovery before restarting the target server, especially if the target is reintroduced as a standby of the source. If you restart the server after the rewind operation has finished but without configuring recovery, the target may again diverge from the primary.

pg\_rewind will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys and certificates. If such files are present on the target server it is recommended to remove them before running pg\_rewind. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

## Options

pg\_rewind accepts the following command-line arguments:

**-D *directory***  
**--target-pgdata=*directory***

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running pg\_rewind

**--source-pgdata=*directory***

Specifies the file system path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

**--source-server=*connstr***

Specifies a libpq connection string to connect to the source PostgreSQL server to synchronize the target with. The connection must be a normal (non-replication) connection with a role having sufficient permissions to execute the functions used by pg\_rewind on the source server (see Notes section for details) or a superuser role. This option requires the source server to be running and accepting connections.

**-R**  
**--write-recovery-conf**

Create `standby.signal` and append connection settings to `postgresql.auto.conf` in the output directory. The dbname will be recorded only if the dbname was specified explicitly in the connection string or environment variable. **--source-server** is mandatory with this option.

**-n**  
**--dry-run**

Do everything except actually modifying the target directory.

**-N**  
**--no-sync**

By default, pg\_rewind will wait for all files to be written safely to disk. This option causes pg\_rewind to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation.

**-P**  
**--progress**

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.

**-c**  
**--restore-target-wal**

Use `restore_command` defined in the target cluster configuration to retrieve WAL files from the WAL archive if these files are no longer available in the `pg_wal` directory.

`--config-file=filename`

Use the specified main server configuration file for the target cluster. This affects `pg_rewind` when it uses internally the `postgres` command for the rewind operation on this cluster (when retrieving `restore_command` with the option `-c/--restore-target-wal` and when forcing a completion of crash recovery).

`--debug`

Print verbose debugging output that is mostly useful for developers debugging `pg_rewind`.

`--no-ensure-shutdown`

`pg_rewind` requires that the target server is cleanly shut down before rewinding. By default, if the target server is not shut down cleanly, `pg_rewind` starts the target server in single-user mode to complete crash recovery first, and stops it. By passing this option, `pg_rewind` skips this and errors out immediately if the server is not cleanly shut down. Users are expected to handle the situation themselves in that case.

`--sync-method=method`

When set to `fsync`, which is the default, `pg_rewind` will recursively open and synchronize all files in the data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the data directory, the WAL files, and each tablespace. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-V`

`--version`

Display version information, then exit.

`-?`

`--help`

Show help, then exit.

## Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by `libpq` (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

When executing `pg_rewind` using an online cluster as source, a role having sufficient permissions to execute the functions used by `pg_rewind` on the source cluster can be used instead of a superuser. Here is how to create such a role, named `rewind_user` here:

```
CREATE USER rewind_user LOGIN;
GRANT EXECUTE ON function pg_catalog.pg_ls_dir(text, boolean,
boolean) TO rewind_user;
```

```
GRANT EXECUTE ON function pg_catalog.pg_stat_file(text, boolean) TO
rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_read_binary_file(text) TO
rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_read_binary_file(text,
bigint, bigint, boolean) TO rewind_user;
```

## How It Works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster's timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off. If some of the WAL files are no longer available, try re-running `pg_rewind` with the `-C` option to search for the missing files in the WAL archive.
2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`). Relation files are now in a state equivalent to the moment of the last completed checkpoint prior to the point at which the WAL timelines of the source and target diverged plus the current state on the source of any blocks changed on the target after that divergence.
3. Copy all other files, including new relation files, WAL segments, `pg_xact`, and configuration files from the source cluster to the target cluster. Similarly to base backups, the contents of the directories `pg_dynshmem/`, `pg_notify/`, `pg_replslot/`, `pg_serial/`, `pg_snapshots/`, `pg_stat_tmp/`, and `pg_subtrans/` are omitted from the data copied from the source cluster. The files `backup_label`, `tablespace_map`, `pg_internal.init`, `postmaster.opts`, `postmaster.pid` and `.DS_Store` as well as any file or directory beginning with `pgsql_tmp`, are omitted.
4. Create a `backup_label` file to begin WAL replay at the checkpoint created at failover and configure the `pg_control` file with a minimum consistency LSN defined as the result of `pg_current_wal_insert_lsn()` when rewinding from a live source or the last checkpoint LSN when rewinding from a stopped source.
5. When starting the target, PostgreSQL replays all the required WAL, resulting in a data directory in a consistent state.

# pg\_test\_fsync

pg\_test\_fsync — determine fastest wal\_sync\_method for PostgreSQL

## Synopsis

pg\_test\_fsync [*option*...]

## Description

pg\_test\_fsync is intended to give you a reasonable idea of what the fastest wal\_sync\_method is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by pg\_test\_fsync might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their write-ahead logs. pg\_test\_fsync reports average file sync operation time in microseconds for each wal\_sync\_method, which can also be used to inform efforts to optimize the value of commit\_delay.

## Options

pg\_test\_fsync accepts the following command-line options:

-f  
--filename

Specifies the file name to write test data in. This file should be in the same file system that the pg\_wal directory is or will be placed in. (pg\_wal contains the WAL files.) The default is pg\_test\_fsync.out in the current directory.

-s  
--secs-per-test

Specifies the number of seconds for each test. The more time per test, the greater the test's accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.

-V  
--version

Print the pg\_test\_fsync version and exit.

-?  
--help

Show help about pg\_test\_fsync command line arguments, and exit.

## Environment

The environment variable PG\_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

# pg\_test\_timing

pg\_test\_timing — measure timing overhead

## Synopsis

pg\_test\_timing [*option...*]

## Description

pg\_test\_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

## Options

pg\_test\_timing accepts the following command-line options:

-d *duration*  
--duration=*duration*

Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

-V  
--version

Print the pg\_test\_timing version and exit.

-?  
--help

Show help about pg\_test\_timing command line arguments, and exit.

## Usage

### Interpreting Results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

```
Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 ns
Histogram of timing durations:
  < us    % of total    count
    1      96.40465    80435604
    2       3.59518     2999652
    4       0.00015        126
    8       0.00002         13
   16       0.00000          2
```

Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (ns), while the individual timing calls can only resolve down to one microsecond (us).

## Measuring Executor Timing Overhead

When the query executor is running a statement using `EXPLAIN ANALYZE`, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the `psql` program:

```
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

## Changing Time Sources

On some newer Linux systems, it's possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```
# cat /sys/devices/system/clocksource/clocksource0/
available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/
current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 ns
Histogram of timing durations:
  < us    % of total    count
    1      27.84870    1155682
    2      72.05956    2990371
    4       0.07810      3241
    8       0.01357      563
   16       0.00007        3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That's 1061 ns of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones,

the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it's backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/
available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
  < us  % of total  count
      1    90.23734 27694571
      2    9.75277 2993204
      4    0.00981   3010
      8    0.00007    22
     16    0.00000     1
     32    0.00000     1
```

## Clock Hardware and Timing Accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that's inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn't default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it's known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it's available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the `acpi_pm`. The clock derived from `acpi_pm` will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

# pg\_upgrade

pg\_upgrade — upgrade a PostgreSQL server instance

## Synopsis

```
pg_upgrade -b oldbindir [-B newbindir] -d oldconfigdir -D newconfigdir [option...]
```

## Description

pg\_upgrade (formerly called pg\_migrator) allows data stored in PostgreSQL data files to be upgraded to a later PostgreSQL major version without the data dump/restore typically required for major version upgrades, e.g., from 12.14 to 13.10 or from 14.9 to 15.5. It is not required for minor version upgrades, e.g., from 12.7 to 12.8 or from 14.1 to 14.5.

Major PostgreSQL releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg\_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg\_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg\_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g., by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg\_upgrade.

pg\_upgrade supports upgrades from 9.2.X and later to the current major release of PostgreSQL, including snapshot and beta releases.

### Warning

Upgrading a cluster causes the destination to execute arbitrary code of the source superusers' choice. Ensure that the source superusers are trusted before upgrading.

## Options

pg\_upgrade accepts the following command-line arguments:

```
-b bindir  
--old-bindir=bindir
```

the old PostgreSQL executable directory; environment variable `PGBINOLD`

```
-B bindir  
--new-bindir=bindir
```

the new PostgreSQL executable directory; default is the directory where pg\_upgrade resides; environment variable `PGBINNEW`

```
-c  
--check
```

check clusters only, don't change any data

`-d configdir`  
`--old-datadir=configdir`

the old database cluster configuration directory; environment variable PGDATAOLD

`-D configdir`  
`--new-datadir=configdir`

the new database cluster configuration directory; environment variable PGDATANEW

`-j njobs`  
`--jobs=njobs`

number of simultaneous connections and processes/threads to use

`-k`  
`--link`

use hard links instead of copying files to the new cluster

`-N`  
`--no-sync`

By default, `pg_upgrade` will wait for all files of the upgraded cluster to be written safely to disk. This option causes `pg_upgrade` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation.

`-o options`  
`--old-options options`

options to be passed directly to the old `postgres` command; multiple option invocations are appended

`-O options`  
`--new-options options`

options to be passed directly to the new `postgres` command; multiple option invocations are appended

`-p port`  
`--old-port=port`

the old cluster port number; environment variable PGPORTOLD

`-P port`  
`--new-port=port`

the new cluster port number; environment variable PGPORTNEW

`-r`  
`--retain`

retain SQL and log files even after successful completion

`-s dir`  
`--socketdir=dir`

directory to use for postmaster sockets during upgrade; default is current working directory; environment variable PGSOCKETDIR

`-U username`

`--username=username`

cluster's install user name; environment variable PGUSER

`-v`

`--verbose`

enable verbose internal logging

`-V`

`--version`

display version information, then exit

`--clone`

Use efficient file cloning (also known as “reflinks” on some systems) instead of copying files to the new cluster. This can result in near-instantaneous copying of the data files, giving the speed advantages of `-k/- -link` while leaving the old cluster untouched.

File cloning is only supported on some operating systems and file systems. If it is selected but not supported, the `pg_upgrade` run will error. At present, it is supported on Linux (kernel 4.5 or later) with Btrfs and XFS (on file systems created with reflink support), and on macOS with APFS.

`--copy`

Copy files to the new cluster. This is the default. (See also `--link`, `--clone`, `--copy-file-range`, and `--swap`.)

`--copy-file-range`

Use the `copy_file_range` system call for efficient copying. On some file systems this gives results similar to `--clone`, sharing physical disk blocks, while on others it may still copy blocks, but do so via an optimized path. At present, it is supported on Linux and FreeBSD.

`--no-statistics`

Do not restore statistics from the old cluster into the new cluster.

`--set-char-signedness=option`

Manually set the default char signedness of new clusters. Possible values are `signed` and `unsigned`.

In the C language, the default signedness of the `char` type (when not explicitly specified) varies across platforms. For example, `char` defaults to `signed char` on x86 CPUs but to `unsigned char` on ARM CPUs.

Starting from PostgreSQL 18, database clusters maintain their own default char signedness setting, which can be used to ensure consistent behavior across platforms with different default char signedness. By default, `pg_upgrade` preserves the char signedness setting when upgrading from an existing cluster. However, when upgrading from PostgreSQL 17 or earlier, `pg_upgrade` adopts the char signedness of the platform on which it was built.

This option allows you to explicitly set the default char signedness for the new cluster, overriding any inherited values. There are two specific scenarios where this option is relevant:

- If you are planning to migrate to a different platform after the upgrade, you should not use this option. The default behavior is right in this case. Instead, perform the upgrade on the original

platform without this flag, and then migrate the cluster afterward. This is the recommended and safest approach.

- If you have already migrated the cluster to a platform with different char signedness (for example, from an x86-based system to an ARM-based system), you should use this option to specify the signedness matching the original platform's default char signedness. Additionally, it's essential not to modify any data files between migrating data files and running `pg_upgrade`. `pg_upgrade` should be the first operation that starts the cluster on the new platform.

#### `--swap`

Move the data directories from the old cluster to the new cluster. Then, replace the catalog files with those generated for the new cluster. This mode can outperform `--link`, `--clone`, `--copy`, and `--copy-file-range`, especially on clusters with many relations.

However, this mode creates many garbage files in the old cluster, which can prolong the file synchronization step if `--sync-method=syncfs` is used. Therefore, it is recommended to use `--sync-method=fsync` with `--swap`.

Additionally, once the file transfer step begins, the old cluster will be destructively modified and therefore will no longer be safe to start. See Step 17 for details.

#### `--sync-method=method`

When set to `fsync`, which is the default, `pg_upgrade` will recursively open and synchronize all files in the upgraded cluster's data directory. The search for files will follow symbolic links for the WAL directory and each configured tablespace.

On Linux, `syncfs` may be used instead to ask the operating system to synchronize the whole file systems that contain the upgraded cluster's data directory, its WAL files, and each tablespace. See `recovery_init_sync_method` for information about the caveats to be aware of when using `syncfs`.

This option has no effect when `--no-sync` is used.

`-?`

`--help`

show help, then exit

## Usage

These are the steps to perform an upgrade with `pg_upgrade`:

### Note

The steps to upgrade *logical replication clusters* are not covered here; refer to Section 29.13 for details.

#### 1. Optionally move the old cluster

If you are using a version-specific installation directory, e.g., `/opt/PostgreSQL/18`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

If your installation directory is not version-specific, e.g., `/usr/local/pgsql`, it is necessary to move the current PostgreSQL install directory so it does not interfere with the new PostgreSQL

installation. Once the current PostgreSQL server is shut down, it is safe to rename the PostgreSQL installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:

```
mv /usr/local/pgsql /usr/local/pgsql.old
```

to rename the directory.

**2. For source installs, build the new version**

Build the new PostgreSQL source with `configure` flags that are compatible with the old cluster. `pg_upgrade` will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

**3. Install the new PostgreSQL binaries**

Install the new server's binaries and support files. `pg_upgrade` is included in a default installation.

For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:

```
make prefix=/usr/local/pgsql.new install
```

**4. Initialize the new PostgreSQL cluster**

Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

**5. Install extension shared object files**

Many extensions and custom modules, whether from `contrib` or another source, use shared object files (or DLLs), e.g., `pgcrypto.so`. If the old cluster used these, shared object files matching the new server binary must be installed in the new cluster, usually via operating system commands. Do not load the schema definitions, e.g., `CREATE EXTENSION pgcrypto`, because these will be duplicated from the old cluster. If extension updates are available, `pg_upgrade` will report this and create a script that can be run later to update them.

**6. Copy custom full-text search files**

Copy any custom full text search files (dictionary, synonym, thesaurus, stop words) from the old to the new cluster.

**7. Adjust authentication**

`pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 32.16).

**8. Stop both servers**

Make sure both database servers are stopped using, on Unix, e.g.:

```
pg_ctl -D /opt/PostgreSQL/12 stop
pg_ctl -D /opt/PostgreSQL/18 stop
```

or on Windows, using the proper service names:

```
NET STOP postgresql-12
```

## NET STOP postgresql-18

Streaming replication and log-shipping standby servers must be running during this shutdown so they receive all changes.

### 9. Prepare for standby server upgrades

If you are upgrading standby servers using methods outlined in section Step 11, verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. Also, make sure `wal_level` is not set to `minimal` in the `postgresql.conf` file on the new primary cluster.

### 10. Run pg\_upgrade

Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster's data and executable (`bin`) directories. You can also specify user and port values, and whether you want the data files linked, cloned, or swapped instead of the default copy behavior.

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_wal` can be on different file systems.) Clone mode provides the same speed and disk space advantages but does not cause the old cluster to be unusable once the new cluster is started. Clone mode also requires that the old and new data directories be in the same file system. This mode is only available on certain operating systems and file systems. Swap mode may be the fastest if there are many relations, but you will not be able to access your old cluster once the file transfer step begins. Swap mode also requires that the old and new cluster data directories be in the same file system.

Setting `--jobs` to 2 or higher allows `pg_upgrade` to process multiple databases and tablespaces in parallel. A good starting point is the number of CPU cores on the machine. This option can substantially reduce the upgrade time for multi-database and multi-tablespace servers.

For Windows users, you must be logged into an administrative account, and then run `pg_upgrade` with quoted directories, e.g.:

```
pg_upgrade.exe
--old-datadir "C:/Program Files/PostgreSQL/12/data"
--new-datadir "C:/Program Files/PostgreSQL/18/data"
--old-bindir "C:/Program Files/PostgreSQL/12/bin"
--new-bindir "C:/Program Files/PostgreSQL/18/bin"
```

Once started, `pg_upgrade` will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link, clone, copy-file-range, or swap mode, you should use the option `--link`, `--clone`, `--copy-file-range`, or `--swap` with `--check` to enable mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. `pg_upgrade` defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, `pg_upgrade` will exit and you will have to revert to the old cluster as outlined in Step 17 below. To try `pg_upgrade` again, you will

need to modify the old cluster so the `pg_upgrade` schema restore succeeds. If the problem is a `contrib` module, you might need to uninstall the `contrib` module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

## 11. Upgrade streaming replication and log-shipping standby servers

If you used link mode and have Streaming Replication (see Section 26.2.5) or Log-Shipping (see Section 26.2) standby servers, you can follow these steps to quickly upgrade them. You will not be running `pg_upgrade` on the standby servers, but rather `rsync` on the primary. Do not start any servers yet.

If you did *not* use link mode, do not have or do not want to use `rsync`, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once `pg_upgrade` completes and the new primary is running.

### 1. Install the new PostgreSQL binaries on standby servers

Make sure the new binaries and support files are installed on all standby servers.

### 2. Make sure the new standby data directories do *not* exist

Make sure the new standby data directories do *not* exist or are empty. If `initdb` was run, delete the standby servers' new data directories.

### 3. Install extension shared object files

Install the same extension shared object files on the new standbys that you installed in the new primary cluster.

### 4. Stop standby servers

If the standby servers are still running, stop them now using the above instructions.

### 5. Save configuration files

Save any configuration files from the old standbys' configuration directories you need to keep, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`, `pg_hba.conf`, because these will be overwritten or removed in the next step.

### 6. Run `rsync`

When using link mode, standby servers can be quickly upgraded using `rsync`. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the *primary* for each standby server:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster new_cluster remote_dir
```

where `old_cluster` and `new_cluster` are relative to the current directory on the primary, and `remote_dir` is *above* the old and new cluster directories on the standby. The directory structure under the specified directories on the primary and standbys must match. Consult the `rsync` manual page for details on specifying the remote directory, e.g.,

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/PostgreSQL/12 \
/opt/PostgreSQL/18 standby.example.com:/opt/PostgreSQL
```

You can verify what the command will do using rsync's `--dry-run` option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

What this does is to record the links created by pg\_upgrade's link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby's old cluster and creates links for them in the standby's new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don't normally exist on standby servers.

If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/pg_tblsp/PG_12_201909212 \
        /vol1/pg_tblsp/PG_18_202307071 standby.example.com:/vol1/pg_tblsp
```

If you have relocated `pg_wal` outside the data directories, rsync must be run on those directories too.

#### 7. **Configure streaming replication and log-shipping standby servers**

Configure the servers for log shipping. (You do not need to run `pg_backup_start()` and `pg_backup_stop()` or take a file system backup as the standbys are still synchronized with the primary.) If the old primary is prior to version 17.0, then no slots on the primary are copied to the new standby, so all the slots on the old standby must be recreated manually. If the old primary is version 17.0 or later, then only logical slots on the primary are copied to the new standby, but other slots on the old standby are not copied, so must be recreated manually.

#### 12. **Restore `pg_hba.conf`**

If you modified `pg_hba.conf`, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`.

#### 13. **Start the new server**

The new server can now be safely started, and then any rsync'ed standby servers.

#### 14. **Post-upgrade processing**

If any post-upgrade processing is required, pg\_upgrade will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```
psql --username=postgres --file=script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

**Caution**

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

**15. Statistics**

Unless the `--no-statistics` option is specified, `pg_upgrade` will transfer most optimizer statistics from the old cluster to the new cluster. This does not transfer all statistics, such as those created explicitly with `CREATE STATISTICS`, custom statistics added by an extension, or statistics collected by the cumulative statistics system.

Because not all statistics are transferred by `pg_upgrade`, you will be instructed to run commands to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

First, use `vacuumdb --all --analyze-in-stages --missing-stats-only` to quickly generate minimal optimizer statistics for relations without any. Then, use `vacuumdb --all --analyze-only` to ensure all relations have updated cumulative statistics for triggering vacuum and analyze. For both commands, the use of `--jobs` can speed it up. If `vacuum_cost_delay` is set to a non-zero value, this can be overridden to speed up statistics generation using `PGOPTIONS`, e.g., `PGOPTIONS='-c vacuum_cost_delay=0' vacuumdb ...`

**16. Delete old cluster**

Once you are satisfied with the upgrade, you can delete the old cluster's data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g., `bin`, `share`).

**17. Reverting to old cluster**

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If the `--check` option was used, the old cluster was unmodified; it can be restarted.
- If neither `--link` nor `--swap` was used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was used, the data files might be shared between the old and new cluster:
  - If `pg_upgrade` aborted before linking started, the old cluster was unmodified; it can be restarted.
  - If you did *not* start the new cluster, the old cluster was unmodified except that, when linking started, a `.old` suffix was appended to `$PGDATA/global/pg_control`. To reuse the old cluster, remove the `.old` suffix from `$PGDATA/global/pg_control`; you can then restart the old cluster.
  - If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.
- If the `--swap` option was used, the old cluster might be destructively modified:
  - If `pg_upgrade` aborts before reporting that the old cluster is no longer safe to start, the old cluster was unmodified; it can be restarted.

- If `pg_upgrade` has reported that the old cluster is no longer safe to start, the old cluster was destructively modified. The old cluster will need to be restored from backup in this case.

## Environment

Some environment variables can be used to provide defaults for command-line options:

### PGBINOLD

The old PostgreSQL executable directory; option `-b/--old-bindir`.

### PGBINNEW

The new PostgreSQL executable directory; option `-B/--new-bindir`.

### PGDATAOLD

The old database cluster configuration directory; option `-d/--old-datadir`.

### PGDATANEW

The new database cluster configuration directory; option `-D/--new-datadir`.

### PGPORTOLD

The old cluster port number; option `-p/--old-port`.

### PGPORTNEW

The new cluster port number; option `-P/--new-port`.

### PGSOCKETDIR

Directory to use for postmaster sockets during upgrade; option `-s/--socketdir`.

### PGUSER

Cluster's install user name; option `-U/--username`.

## Notes

`pg_upgrade` creates various working files, such as schema dumps, stored within `pg_upgrade_output.d` in the directory of the new cluster. Each run creates a new subdirectory named with a timestamp formatted as per ISO 8601 (`%Y%m%dT%H%M%S`), where all its generated files are stored. `pg_upgrade_output.d` and its contained files will be removed automatically if `pg_upgrade` completes successfully; but in the event of trouble, the files there may provide useful debugging information.

`pg_upgrade` launches short-lived postmasters in the old and new data directories. Temporary Unix socket files for communication with these postmasters are, by default, made in the current working directory. In some situations the path name for the current directory might be too long to be a valid socket name. In that case you can use the `-S` option to put the socket files in some directory with a shorter path name. For security, be sure that that directory is not readable or writable by any other users. (This is not supported on Windows.)

All failure, rebuild, and reindex cases will be reported by `pg_upgrade` if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

pg\_upgrade does not support upgrading of databases containing table columns using these `reg*` OID-referencing system data types:

```
regcollation
regconfig
regdictionary
regnamespace
regoper
regoperator
regproc
regprocedure
```

(`regclass`, `regrole`, and `regtype` can be upgraded.)

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, consider using the clone mode. If that is not available, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the old server and run `rsync --checksum` again to update the copy with any changes to make it consistent. (`--checksum` is necessary because `rsync` only has file modification-time granularity of one second.) You might want to exclude some files, e.g., `postmaster.pid`, as documented in Section 25.3.4. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

# pg\_waldump

`pg_waldump` — display a human-readable rendering of the write-ahead log of a PostgreSQL database cluster

## Synopsis

```
pg_waldump [option...] [startseg [endseg]]
```

## Description

`pg_waldump` displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

## Options

The following command-line options control the location and format of the output:

*startseg*

Start reading at the specified WAL segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

*endseg*

Stop after reading the specified WAL segment file.

**-b**

**--bkp-details**

Output detailed information about backup blocks.

**-B block**

**--block=block**

Only display records that modify the given block. The relation must also be provided with **--relation** or **-R**.

**-e end**

**--end=end**

Stop reading at the specified WAL location, instead of reading to the end of the log stream.

**-f**

**--follow**

After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

**-F fork**

**--fork=fork**

Only display records that modify blocks in the given fork. The valid values are `main` for the main fork, `fsm` for the free space map, `vm` for the visibility map, and `init` for the init fork.

`-n limit`  
`--limit=limit`

Display the specified number of records, then stop.

`-p path`  
`--path=path`

Specifies a directory to search for WAL segment files or a directory with a `pg_wal` subdirectory that contains such files. The default is to search in the current directory, the `pg_wal` subdirectory of the current directory, and the `pg_wal` subdirectory of PGDATA.

`-q`  
`--quiet`

Do not print any output, except for errors. This option can be useful when you want to know whether a range of WAL records can be successfully parsed but don't care about the record contents.

`-r rmgr`  
`--rmgr=rmgr`

Only display records generated by the specified resource manager. You can specify the option multiple times to select multiple resource managers. If `list` is passed as name, print a list of valid resource manager names, and exit.

Extensions may define custom resource managers, but `pg_waldump` does not load the extension module and therefore does not recognize custom resource managers by name. Instead, you can specify the custom resource managers as `custom###` where `###` is the three-digit resource manager ID. Names of this form will always be considered valid.

`-R tblspc/db/rel`  
`--relation=tblspc/db/rel`

Only display records that modify blocks in the given relation. The relation is specified with tablespace OID, database OID, and relfilenode separated by slashes, for example `1234/12345/12345`. This is the same format used for relations in the program's output.

`-s start`  
`--start=start`

WAL location at which to start reading. The default is to start reading the first valid WAL record found in the earliest file found.

`-t timeline`  
`--timeline=timeline`

Timeline from which to read WAL records. The default is to use the value in `startseg`, if that is specified; otherwise, the default is 1. The value can be specified in decimal or hexadecimal, for example `17` or `0x11`.

`-V`  
`--version`

Print the `pg_waldump` version and exit.

`-w`  
`--fullpage`

Only display records that include full page images.

`-x xid`  
`--xid=xid`

Only display records marked with the given transaction ID.

`-z`  
`--stats[=record]`

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

If `pg_waldump` is terminated by signal `SIGINT` (**Control+C**), the summary of the statistics computed is displayed up to the termination point. This operation is not supported on Windows.

`--save-fullpage=save_path`

Save full page images found in the WAL records to the *save\_path* directory. The images saved are subject to the same filtering and limiting criteria as the records displayed.

The full page images are saved with the following file name format: *TIMELINE-LSN.RELTABLESPACE.DATOID.RELNODE.BLKNO\_FORK* The file names are composed of the following parts:

| Component     | Description                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| TIMELINE      | The timeline of the WAL segment file where the record is located formatted as one 8-character hexadecimal number %08X                       |
| LSN           | The LSN of the record with this image, formatted as two 8-character hexadecimal numbers %08X-%08X                                           |
| RELTABLESPACE | tablespace OID of the block                                                                                                                 |
| DATOID        | database OID of the block                                                                                                                   |
| RELNODE       | filenode of the block                                                                                                                       |
| BLKNO         | block number of the block                                                                                                                   |
| FORK          | The name of the fork the full page image came from, such as <code>main</code> , <code>fsm</code> , <code>vm</code> , or <code>init</code> . |

`-?`  
`--help`

Show help about `pg_waldump` command line arguments, and exit.

## Environment

`PGDATA`

Data directory; see also the `-p` option.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

pg\_waldump cannot read WAL files with suffix `.partial`. If those files need to be read, `.partial` suffix needs to be removed from the file name.

# pg\_walsummary

pg\_walsummary — print contents of WAL summary files

## Synopsis

pg\_walsummary [*option...*] [*file...*]

## Description

pg\_walsummary is used to print the contents of WAL summary files. These binary files are found in the `pg_wal/summaries` subdirectory of the data directory, and can be converted to text using this tool. This is not ordinarily necessary, since WAL summary files primarily exist to support incremental backup, but it may be useful for debugging purposes.

A WAL summary file is indexed by tablespace OID, relation OID, and relation fork. For each relation fork, it stores the list of blocks that were modified by WAL within the range summarized in the file. It can also store a "limit block," which is 0 if the relation fork was created or truncated within the relevant WAL range, and otherwise the shortest length to which the relation fork was truncated. If the relation fork was not created, deleted, or truncated within the relevant WAL range, the limit block is undefined or infinite and will not be printed by this tool.

## Options

-i  
--individual

By default, pg\_walsummary prints one line of output for each range of one or more consecutive modified blocks. This can make the output a lot briefer, since a relation where all blocks from 0 through 999 were modified will produce only one line of output rather than 1000 separate lines. This option requests a separate line of output for every modified block.

-q  
--quiet

Do not print any output, except for errors. This can be useful when you want to know whether a WAL summary file can be successfully parsed but don't care about the contents.

-V  
--version

Display version information, then exit.

-?  
--help

Shows help about pg\_walsummary command line arguments, and exits.

## Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

# postgres

postgres — PostgreSQL database server

## Synopsis

postgres [*option*...]

## Description

`postgres` is the PostgreSQL database server. In order for a client application to access a database it connects (over a network or locally) to a running `postgres` instance. The `postgres` instance then starts a separate server process to handle the connection.

One `postgres` instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one `postgres` instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When `postgres` starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by `initdb`. Other possible file layouts are discussed in Section 19.2.

By default `postgres` starts in the foreground and prints log messages to the standard error stream. In practical applications `postgres` should be started as a background process, perhaps at boot time.

The `postgres` command can also be called in single-user mode. The primary use for this mode is during bootstrapping by `initdb`. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

## Options

`postgres` accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 19. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as `postgres` command-line options.

## General Purpose

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `shared_buffers` configuration parameter.

`-c name=value`

Sets a named run-time parameter. The configuration parameters supported by PostgreSQL are described in Chapter 19. Most of the other command line options are in fact short forms of such a parameter assignment. `-C` can appear multiple times to set multiple parameters.

**-C *name***

Prints the value of the named run-time parameter, and exits. (See the **-c** option above for details.) This returns values from `postgresql.conf`, modified by any parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This can be used on a running server for most parameters. However, the server must be shut down for some runtime-computed parameters (e.g., `shared_memory_size`, `shared_memory_size_in_huge_pages`, and `wal_segment_size`).

This option is meant for other programs that interact with a server instance, such as `pg_ctl`, to query configuration parameter values. User-facing applications should instead use **SHOW** or the `pg_settings` view.

**-d *debug-level***

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass **-d 0** for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

**-D *datadir***

Specifies the file system location of the database configuration files. See Section 19.2 for details.

**-e**

Sets the default date style to “European”, that is **DMY** ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

**-F**

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

**-h *hostname***

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

**-i**

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via **-h**.

This option is deprecated since it does not allow access to the full functionality of `listen_addresses`. It's usually better to set `listen_addresses` directly.

**-k *directory***

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally `/tmp`, but that can be

changed at build time. Specifying this option is equivalent to setting the `unix_socket_directories` configuration parameter.

**-l**

Enables secure connections using SSL. PostgreSQL must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 18.9.

**-N *max-connections***

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `max_connections` configuration parameter.

**-p *port***

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

**-s**

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

**-S *work-mem***

Specifies the base amount of memory to be used by sorts and hash tables before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in Section 19.4.1.

**-V**

**--version**

Print the `postgres` version and exit.

**--name=*value***

Sets a named run-time parameter; a shorter form of `-c`.

**--describe-config**

This option dumps out the server's internal configuration variables, descriptions, and defaults in tab-delimited COPY format. It is designed primarily for use by administration tools.

**-?**

**--help**

Show help about `postgres` command line arguments, and exit.

## Semi-Internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by PostgreSQL system developers. Furthermore, these options might change or be removed in a future release without notice.

**-f { s | i | o | b | t | n | m | h }**

Forbids the use of particular scan and join methods: `s` and `i` disable sequential and index scans respectively, `o`, `b` and `t` disable index-only scans, bitmap index scans, and TID scans respectively, while `n`, `m`, and `h` disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the `-fs` and `-fn` options simply discourage the optimizer from using those plan types if it has any other alternative.

**-O**

Allows the structure of system tables to be modified. This is used by `initdb`.

**-P**

Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.

**-t pa[rser] | pl[anner] | e[xecutor]**

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the `-S` option.

**-T**

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate, by sending them SIGQUIT signals. With this option, SIGABRT will be sent instead, resulting in production of core dump files.

**-v *protocol***

Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.

**-W *seconds***

A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

## Options for Single-User Mode

The following options only apply to the single-user mode (see Single-User Mode below).

**--single**

Selects the single-user mode. This must be the first argument on the command line.

***database***

Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

**-E**

Echo all commands to standard output before executing them.

**-j**

Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.

**-r *filename***

Send all server log output to *filename*. This option is only honored when supplied as a command-line option.

## Environment

### PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

### PGDATA

Default data directory location

### PGDATESTYLE

Default value of the `DateStyle` run-time parameter. (The use of this environment variable is deprecated.)

### PGPORT

Default port number (preferably set in the configuration file)

## Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 18.4. You might be able to postpone reconfiguring your kernel by decreasing `shared_buffers` to reduce the shared memory consumption of PostgreSQL, and/or by reducing `max_connections` to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-PostgreSQL process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

## Notes

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, *do not* use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect

all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in Section 9.28.2 for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal *should not* be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

## Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of PostgreSQL will provide a workaround if this is not fixed.

## Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options  
my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the `-j` command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you've entered will be executed as a single transaction.

To quit the session, type EOF (**Control+D**, usually). If you've entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

## Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start postgres with a specific port, e.g., 1234:

```
$ postgres -p 1234
```

To connect to this server using psql, specify this port with the -p option:

```
$ psql -p 1234
```

or set the environment variable PGPORT:

```
$ export PGPORT=1234  
$ psql
```

Named run-time parameters can be set in either of these styles:

```
$ postgres -c work_mem=1234  
$ postgres --work-mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

# Chapter 51. Overview of PostgreSQL Internals

## Author

This chapter originated as part of [sim98] Stefan Simkovics' Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of PostgreSQL. After having read the following sections you should have an idea of how a query is processed. This chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

## 51.1. The Path of a Query

Here we give a short overview of the stages a query has to pass to obtain a result.

1. A connection from an application program to the PostgreSQL server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.
2. The *parser stage* checks the query transmitted by the application program for correct syntax and creates a *query tree*.
3. The *rewrite system* takes the query tree created by the parser stage and looks for any *rules* (stored in the *system catalogs*) to apply to the query tree. It performs the transformations given in the *rule bodies*.

One application of the rewrite system is in the realization of *views*. Whenever a query against a view (i.e., a *virtual table*) is made, the rewrite system rewrites the user's query to a query that accesses the *base tables* given in the *view definition* instead.

4. The *planner/optimizer* takes the (rewritten) query tree and creates a *query plan* that will be the input to the *executor*.

It does so by first creating all possible *paths* leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the *plan tree* and retrieves rows in the way represented by the plan. The executor makes use of the *storage system* while scanning relations, performs *sorts* and *joins*, evaluates *qualifications* and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of PostgreSQL's internal control and data structures.

## 51.2. How Connections Are Established

PostgreSQL implements a “process per user” client/server model. In this model, every *client process* connects to exactly one *backend process*. As we do not know ahead of time how many connections will be made, we have to use a “supervisor process” that spawns a new backend process every time a

connection is requested. This supervisor process is called *postmaster* and listens at a specified TCP/IP port for incoming connections. Whenever it detects a request for a connection, it spawns a new backend process. Those backend processes communicate with each other and with other processes of the *instance* using *semaphores* and *shared memory* to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the PostgreSQL protocol described in Chapter 54. Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established, the client process can send a query to the backend process it's connected to. The query is transmitted using plain text, i.e., there is no parsing done in the client. The backend process parses the query, creates an *execution plan*, executes the plan, and returns the retrieved rows to the client by transmitting them over the established connection.

## 51.3. The Parser Stage

The *parser stage* consists of two parts:

- The *parser* defined in `gram.y` and `scan.l` is built using the Unix tools bison and flex.
- The *transformation process* does modifications and augmentations to the data structures returned by the parser.

### 51.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a *parse tree* is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools bison and flex.

The *lexer* is defined in the file `scan.l` and is responsible for recognizing *identifiers*, the *SQL key words* etc. For every key word or identifier that is found, a *token* is generated and handed to the parser.

The parser is defined in the file `gram.y` and consists of a set of *grammar rules* and *actions* that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file `scan.l` is transformed to the C source file `scan.c` using the program flex and `gram.y` is transformed to `gram.c` using bison. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time flex or bison is called.

#### Note

The mentioned transformations and compilations are normally done automatically using the *makefiles* shipped with the PostgreSQL source distribution.

A detailed description of bison or the grammar rules given in `gram.y` would be beyond the scope of this manual. There are many books and documents dealing with flex and bison. You should be familiar with bison before you start to study the grammar given in `gram.y` otherwise you won't understand what happens there.

### 51.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the *transformation process* takes the tree handed back by the parser as input and does the semantic interpretation needed to understand

which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the *query tree*.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (**BEGIN**, **ROLLBACK**, etc.), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as **SELECT** or **UPDATE**), it is okay to start a transaction if we're not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a `FuncCall` node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a `FuncExpr` or `Aggref` node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

## 51.4. The PostgreSQL Rule System

PostgreSQL supports a powerful *rule system* for the specification of *views* and ambiguous *view updates*. Originally the PostgreSQL rule system consisted of two implementations:

- The first one worked using *row level* processing and was implemented deep in the *executor*. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called *query rewriting*. The *rewrite system* is a module that exists between the *parser stage* and the *planner/optimizer*. This technique is still implemented.

The query rewriter is discussed in some detail in Chapter 39, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

## 51.5. Planner/Optimizer

The task of the *planner/optimizer* is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

### Note

In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, PostgreSQL uses a *Genetic Query Optimizer* (see Chapter 61) when the number of joins exceeds a threshold (see `geqo_threshold`).

The planner's search procedure actually works with data structures called *paths*, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged *plan tree* is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

## 51.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPR constant`. If `relation.attribute` happens to match the key of the B-tree index and `OPR` is one of the operators listed in the index's *operator class*, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- *nested loop join*: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)
- *merge join*: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.
- *hash join*: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than `geqo_threshold` relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exists a corresponding join clause in the `WHERE` qualification (i.e., for which a restriction like `where rel1.attr1=rel2.attr2` exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When `geqo_threshold` is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 61. Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do *selection* (discarding rows that do not meet a specified Boolean condition) and *projection* (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the `WHERE` clause and computation of required output expressions to the most appropriate nodes of the plan tree.

## 51.6. Executor

The *executor* takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a `MergeJoin` node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to `lefttree`). The new top node (the top node of the left subplan) is, let's say, a `Sort` node and again recursion is needed to obtain an input row. The child node of the `Sort` might be a `SeqScan` node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The `Sort` node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a `NULL` instead of a row), the `Sort` code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The `MergeJoin` node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the `MergeJoin` node returns `NULL` to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all five basic SQL query types: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. For `SELECT`, the top-level executor code only needs to send each row returned by the query plan tree off to the client. `INSERT . . . SELECT`, `UPDATE`, `DELETE`, and `MERGE` are effectively `SELECT`s under a special top-level plan node called `ModifyTable`.

`INSERT . . . SELECT` feeds the rows up to `ModifyTable` for insertion. For `UPDATE`, the planner arranges that each computed row includes all the updated column values, plus the *TID* (tuple ID, or row ID) of the original target row; this data is fed up to the `ModifyTable` node, which uses the information to create a new updated row and mark the old row deleted. For `DELETE`, the only column that is actually returned by the plan is the *TID*, and the `ModifyTable` node simply uses the *TID* to visit each target row and mark it deleted. For `MERGE`, the planner joins the source and target relations, and includes all column values required by any of the `WHEN` clauses, plus the *TID* of the target row; this data is fed up to the `ModifyTable` node, which uses the information to work out which `WHEN` clause to execute, and then inserts, updates or deletes the target row, as required.

A simple `INSERT . . . VALUES` command creates a trivial plan tree consisting of a single `Result` node, which computes just one result row, feeding that up to `ModifyTable` to perform the insertion.

---

# Chapter 52. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. PostgreSQL's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, `CREATE DATABASE` inserts a row into the `pg_database` catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

## 52.1. Overview

Table 52.1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

**Table 52.1. System Catalogs**

| Catalog Name                         | Purpose                                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------------------|
| <code>pg_aggregate</code>            | aggregate functions                                                                     |
| <code>pg_am</code>                   | relation access methods                                                                 |
| <code>pg_amop</code>                 | access method operators                                                                 |
| <code>pg_amproc</code>               | access method support functions                                                         |
| <code>pg_attrdef</code>              | column default values                                                                   |
| <code>pg_attribute</code>            | table columns (“attributes”)                                                            |
| <code>pg_authid</code>               | authorization identifiers (roles)                                                       |
| <code>pg_auth_members</code>         | authorization identifier membership relationships                                       |
| <code>pg_cast</code>                 | casts (data type conversions)                                                           |
| <code>pg_class</code>                | tables, indexes, sequences, views (“relations”)                                         |
| <code>pg_collation</code>            | collations (locale information)                                                         |
| <code>pg_constraint</code>           | check constraints, unique constraints, primary key constraints, foreign key constraints |
| <code>pg_conversion</code>           | encoding conversion information                                                         |
| <code>pg_database</code>             | databases within this database cluster                                                  |
| <code>pg_db_role_setting</code>      | per-role and per-database settings                                                      |
| <code>pg_default_acl</code>          | default privileges for object types                                                     |
| <code>pg_depend</code>               | dependencies between database objects                                                   |
| <code>pg_description</code>          | descriptions or comments on database objects                                            |
| <code>pg_enum</code>                 | enum label and value definitions                                                        |
| <code>pg_event_trigger</code>        | event triggers                                                                          |
| <code>pg_extension</code>            | installed extensions                                                                    |
| <code>pg_foreign_data_wrapper</code> | foreign-data wrapper definitions                                                        |
| <code>pg_foreign_server</code>       | foreign server definitions                                                              |

| Catalog Name             | Purpose                                                         |
|--------------------------|-----------------------------------------------------------------|
| pg_foreign_table         | additional foreign table information                            |
| pg_index                 | additional index information                                    |
| pg_inherits              | table inheritance hierarchy                                     |
| pg_init_privs            | object initial privileges                                       |
| pg_language              | languages for writing functions                                 |
| pg_largeobject           | data pages for large objects                                    |
| pg_largeobject_metadata  | metadata for large objects                                      |
| pg_namespace             | schemas                                                         |
| pg_opclass               | access method operator classes                                  |
| pg_operator              | operators                                                       |
| pg_opfamily              | access method operator families                                 |
| pg_parameter_acl         | configuration parameters for which privileges have been granted |
| pg_partitioned_table     | information about partition key of tables                       |
| pg_policy                | row-security policies                                           |
| pg_proc                  | functions and procedures                                        |
| pg_publication           | publications for logical replication                            |
| pg_publication_namespace | schema to publication mapping                                   |
| pg_publication_rel       | relation to publication mapping                                 |
| pg_range                 | information about range types                                   |
| pg_replication_origin    | registered replication origins                                  |
| pg_rewrite               | query rewrite rules                                             |
| pg_seclabel              | security labels on database objects                             |
| pg_sequence              | information about sequences                                     |
| pg_shdepend              | dependencies on shared objects                                  |
| pg_shdescription         | comments on shared objects                                      |
| pg_shseclabel            | security labels on shared database objects                      |
| pg_statistic             | planner statistics                                              |
| pg_statistic_ext         | extended planner statistics (definition)                        |
| pg_statistic_ext_data    | extended planner statistics (built statistics)                  |
| pg_subscription          | logical replication subscriptions                               |
| pg_subscription_rel      | relation state for subscriptions                                |
| pg_tablespace            | tablespaces within this database cluster                        |
| pg_transform             | transforms (data type to procedural language conversions)       |
| pg_trigger               | triggers                                                        |
| pg_ts_config             | text search configurations                                      |
| pg_ts_config_map         | text search configurations' token mappings                      |
| pg_ts_dict               | text search dictionaries                                        |
| pg_ts_parser             | text search parsers                                             |
| pg_ts_template           | text search templates                                           |

| Catalog Name    | Purpose                              |
|-----------------|--------------------------------------|
| pg_type         | data types                           |
| pg_user_mapping | mappings of users to foreign servers |

## 52.2. pg\_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

**Table 52.2. pg\_aggregate Columns**

| Column Type<br>Description                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>aggfnoid regproc</code> (references <code>pg_proc.oid</code> )<br>pg_proc OID of the aggregate function                                                                                                                                                                                                                                                                        |
| <code>aggkind char</code><br>Aggregate kind: n for “normal” aggregates, o for “ordered-set” aggregates, or h for “hypothetical-set” aggregates                                                                                                                                                                                                                                       |
| <code>aggnumdirectargs int2</code><br>Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to <code>pronargs</code> , the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates. |

| <code>aggtranstype oid</code> (references <code>pg_type.oid</code> )  | Data type of the aggregate function's internal transition (state) data                                                                                                                                                           |
| <code>aggtransspace int4</code>                                       | Approximate average size (in bytes) of the transition state data, or zero to use a default estimate                                                                                                                              |
| <code>aggmtranstype oid</code> (references <code>pg_type.oid</code> ) | Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)                                                                                                                  |
| <code>aggmtransspace int4</code>                                      | Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate                                                                                                    |
| <code>agginitval text</code>                                          | The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.                           |
| <code>aggminitval text</code>                                         | The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null. |

New aggregate functions are registered with the `CREATE AGGREGATE` command. See Section 36.12 for more information about writing aggregate functions and the meaning of the transition functions, etc.

## 52.3. pg\_am

The catalog `pg_am` stores information about relation access methods. There is one row for each access method supported by the system. Currently, only tables and indexes have access methods. The requirements for table and index access methods are discussed in detail in Chapter 62 and Chapter 63 respectively.

**Table 52.3. `pg_am` Columns**

| Column Type                                                           | Description                                                                                     |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                  | Row identifier                                                                                  |
| <code>amname name</code>                                              | Name of the access method                                                                       |
| <code>amhandler regproc</code> (references <code>pg_proc.oid</code> ) | OID of a handler function that is responsible for supplying information about the access method |
| <code>amtype char</code>                                              | <code>t</code> = table (including materialized views), <code>i</code> = index.                  |

**Note**

Before PostgreSQL 9.6, `pg_am` contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, `pg_index_column_has_property()` and related functions have been added to allow SQL queries to inspect index access method properties; see Table 9.76.

## 52.4. `pg_amop`

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a *search* operator or an *ordering* operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

**Table 52.4. `pg_amop` Columns**

| Column Type                                                                | Description                                                                                                  |
|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                       | Row identifier                                                                                               |

| <code>amoplefttype oid</code> (references <code>pg_type.oid</code> )       | Left-hand input data type of operator                                                                        |
| <code>amoprightrighttype oid</code> (references <code>pg_type.oid</code> ) | Right-hand input data type of operator                                                                       |
| <code>amopstrategy int2</code>                                             | Operator strategy number                                                                                     |
| <code>amoppurpose char</code>                                              | Operator purpose, either <code>s</code> for search or <code>o</code> for ordering                            |
| <code>amopopr oid</code> (references <code>pg_operator.oid</code> )        | OID of the operator                                                                                          |
| <code>amopmethod oid</code> (references <code>pg_am.oid</code> )           | Index access method operator family is for                                                                   |
| <code>amopsortfamily oid</code> (references <code>pg_opfamily.oid</code> ) | The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator |

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying `WHERE indexed_column operator constant`. Obviously, such an operator must return `boolean`, and its left-hand input type must match the index's column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by `ORDER BY indexed_column operator constant`. Such an operator could return any sortable data type, though again its left-hand input type must match the index's column data type. The exact semantics of the `ORDER BY` are specified by the `amopsortfamily` column, which must reference a B-tree operator family for the operator's result type.

**Note**

At present, it's assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., `ASC NULLS LAST`. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprightright` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

## 52.5. `pg_amproc`

The catalog `pg_amproc` stores information about support functions associated with access method operator families. There is one row for each support function belonging to an operator family.

**Table 52.5. `pg_amproc` Columns**

| Column Type                                                              | Description                                       |
|--------------------------------------------------------------------------|---------------------------------------------------|
| <code>oid oid</code>                                                     | Row identifier                                    |
| <code>amprocfamily oid</code> (references <code>pg_opfamily.oid</code> ) | The operator family this entry is for             |
| <code>amprocleftright oid</code> (references <code>pg_type.oid</code> )  | Left-hand input data type of associated operator  |
| <code>amprocrightright oid</code> (references <code>pg_type.oid</code> ) | Right-hand input data type of associated operator |
| <code>amprocnum int2</code>                                              | Support function number                           |
| <code>amproc regproc</code> (references <code>pg_proc.oid</code> )       | OID of the function                               |

The usual interpretation of the `amprocleftright` and `amprocrightright` fields is that they identify the left and right input types of the operator(s) that a particular support function supports. For some access methods these match the input data type(s) of the support function itself, for others not. There is a notion of “default” support functions for an index, which are those with `amprocleftright` and `amprocrightright` both equal to the index operator class's `opcintype`.

## 52.6. `pg_attrdef`

The catalog `pg_attrdef` stores column default expressions and generation expressions. The main information about columns is stored in `pg_attribute`. Only columns for which a default expression or generation expression has been explicitly set will have an entry here.

**Table 52.6. `pg_attrdef` Columns**

| Column Type                                                      | Description                      |
|------------------------------------------------------------------|----------------------------------|
| <code>oid oid</code>                                             | Row identifier                   |
| <code>adrelid oid</code> (references <code>pg_class.oid</code> ) | The table this column belongs to |

| Column Type                                                            | Description                                                                                                                                                                  |
|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>adnum int2</code> (references <code>pg_attribute.attnum</code> ) | The number of the column                                                                                                                                                     |
| <code>adbin pg_node_tree</code>                                        | The column default or generation expression, in <code>nodeToString()</code> representation. Use <code>pg_get_expr(adbin, adrelid)</code> to convert it to an SQL expression. |

## 52.7. pg\_attribute

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

**Table 52.7. pg\_attribute Columns**

| Column Type                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>attrelid oid</code> (references <code>pg_class.oid</code> ) | The table this column belongs to                                                                                                                                                                                                                                                                                                                                                                          |
| <code>attname name</code>                                         | The column name                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>atttypid oid</code> (references <code>pg_type.oid</code> )  | The data type of this column (zero for a dropped column)                                                                                                                                                                                                                                                                                                                                                  |
| <code>attlen int2</code>                                          | A copy of <code>pg_type.typelen</code> of this column's type                                                                                                                                                                                                                                                                                                                                              |
| <code>attnum int2</code>                                          | The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>ctid</code> , have (arbitrary) negative numbers.                                                                                                                                                                                                                                                         |
| <code>atttypmod int4</code>                                       | <code>atttypmod</code> records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need <code>atttypmod</code> .                                                                                     |
| <code>attn_dims int2</code>                                       | Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means "it's an array".)                                                                                                                                                                                                             |
| <code>attbyval bool</code>                                        | A copy of <code>pg_type.typbyval</code> of this column's type                                                                                                                                                                                                                                                                                                                                             |
| <code>attalign char</code>                                        | A copy of <code>pg_type.typalign</code> of this column's type                                                                                                                                                                                                                                                                                                                                             |
| <code>attstorage char</code>                                      | Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.                                                                                                                                                                                                                                 |
| <code>attcompression char</code>                                  | The current compression method of the column. Typically this is <code>'0'</code> to specify use of the current default setting (see <code>default_toast_compression</code> ). Otherwise, <code>'p'</code> selects <code>pglz</code> compression, while <code>'l'</code> selects <code>LZ4</code> compression. However, this field is ignored whenever <code>attstorage</code> does not allow compression. |

| Column Type                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>attnotnull bool</code>                                              | This column has a (possibly invalid) not-null constraint.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>atthasdef bool</code>                                               | This column has a default expression or generation expression, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the expression. (Check <code>attgenerated</code> to determine whether this is a default or a generation expression.)                                                                                                                                                                                        |
| <code>atthasmissing bool</code>                                           | This column has a value which is used where the column is entirely missing from the row, as happens when a column is added with a non-volatile <code>DEFAULT</code> value after the row is created. The actual value used is stored in the <code>attmissingval</code> column.                                                                                                                                                                                                             |
| <code>attidentity char</code>                                             | If a zero byte ( ' '), then not an identity column. Otherwise, <code>a</code> = generated always, <code>d</code> = generated by default.                                                                                                                                                                                                                                                                                                                                                  |
| <code>attgenerated char</code>                                            | If a zero byte ( ' '), then not a generated column. Otherwise, <code>s</code> = stored, <code>v</code> = virtual. A stored generated column is physically stored like a normal column. A virtual generated column is physically stored as a null value, with the actual value being computed at run time.                                                                                                                                                                                 |
| <code>attisdropped bool</code>                                            | This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.                                                                                                                                                                                                                                                                                                           |
| <code>attislocal bool</code>                                              | This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.                                                                                                                                                                                                                                                                                                                                                                   |
| <code>attinhcount int2</code>                                             | The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.                                                                                                                                                                                                                                                                                                                                                                |
| <code>attcollation oid</code> (references <code>pg_collation.oid</code> ) | The defined collation of the column, or zero if the column is not of a collatable data type                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>attstattarget int2</code>                                           | <code>attstattarget</code> controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A null value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, <code>attstattarget</code> is both the target number of “most common values” to collect, and the target number of histogram bins to create. |
| <code>attaclaclitem[]</code>                                              | Column-level access privileges, if any have been granted specifically on this column                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>attoptions text[]</code>                                            | Attribute-level options, as “keyword=value” strings                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>attfdwoptions text[]</code>                                         | Attribute-level foreign data wrapper options, as “keyword=value” strings                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>attmissingval anyarray</code>                                       | This column has a one element array containing the value used when the column is entirely missing from the row, as happens when the column is added with a non-volatile <code>DEFAULT</code> value after the row is created. The value is only used when <code>atthasmissing</code> is true. If there is no value the column is null.                                                                                                                                                     |

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to cope with the situation

where the dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table.

## 52.8. `pg_authid`

The catalog `pg_authid` contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

Chapter 21 contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

**Table 52.8. `pg_authid` Columns**

| Column Type                            | Description                                                                                                                |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                   | Row identifier                                                                                                             |
| <code>rolname name</code>              | Role name                                                                                                                  |
| <code>rolsuper bool</code>             | Role has superuser privileges                                                                                              |
| <code>rolinherit bool</code>           | Role automatically inherits privileges of roles it is a member of                                                          |
| <code>rolcreaterole bool</code>        | Role can create more roles                                                                                                 |
| <code>rolcreatedb bool</code>          | Role can create databases                                                                                                  |
| <code>rolcanlogin bool</code>          | Role can log in. That is, this role can be given as the initial session authorization identifier.                          |
| <code>rolreplication bool</code>       | Role is a replication role. A replication role can initiate replication connections and create and drop replication slots. |
| <code>rolbypassrls bool</code>         | Role bypasses every row-level security policy, see Section 5.9 for more information.                                       |
| <code>rolconnlimit int4</code>         | For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.       |
| <code>rolpassword text</code>          | Encrypted password; null if none. The format depends on the form of encryption used.                                       |
| <code>rolvaliduntil timestamptz</code> | Password expiry time (only used for password authentication); null if no expiration                                        |

For an MD5 encrypted password, `rolpassword` column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user `joe` has password `xyzyz`, PostgreSQL will store the md5 hash of `xyzyzjoe`.

**Warning**

Support for MD5-encrypted passwords is deprecated and will be removed in a future release of PostgreSQL. Refer to Section 20.5 for details about migrating to another password type.

If the password is encrypted with SCRAM-SHA-256, it has the format:

SCRAM-SHA-256\$<iteration count>:<salt>\$<StoredKey>:<ServerKey>

where *salt*, *StoredKey* and *ServerKey* are in Base64 encoded format. This format is the same as that specified by RFC 5803<sup>1</sup>.

## 52.9. pg\_auth\_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

**Table 52.9. pg\_auth\_members Columns**

| Column Type                                         | Description                                                                  |
|-----------------------------------------------------|------------------------------------------------------------------------------|
| <code>oid oid</code>                                | Row identifier                                                               |
| <code>roleid oid (references pg_authid.oid)</code>  | ID of a role that has a member                                               |
| <code>member oid (references pg_authid.oid)</code>  | ID of a role that is a member of <code>roleid</code>                         |
| <code>grantor oid (references pg_authid.oid)</code> | ID of the role that granted this membership                                  |
| <code>admin_option bool</code>                      | True if member can grant membership in <code>roleid</code> to others         |
| <code>inherit_option bool</code>                    | True if the member automatically inherits the privileges of the granted role |
| <code>set_option bool</code>                        | True if the member can SET <code>ROLE</code> to the granted role             |

## 52.10. pg\_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “automatic I/O conversion casts”, those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

<sup>1</sup> <https://datatracker.ietf.org/doc/html/rfc5803>

**Table 52.10. pg\_cast Columns**

| Column Type                             | Description                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid oid                                 | Row identifier                                                                                                                                                                                                                                                                                |
| castsource oid (references pg_type.oid) | OID of the source data type                                                                                                                                                                                                                                                                   |
| casttarget oid (references pg_type.oid) | OID of the target data type                                                                                                                                                                                                                                                                   |
| castfunc oid (references pg_proc.oid)   | The OID of the function to use to perform this cast. Zero is stored if the cast method doesn't require a function.                                                                                                                                                                            |
| castcontext char                        | Indicates what contexts the cast can be invoked in. <b>e</b> means only as an explicit cast (using <b>CAST</b> or <b>::</b> syntax). <b>a</b> means implicitly in assignment to a target column, as well as explicitly. <b>i</b> means implicitly in expressions, as well as the other cases. |
| castmethod char                         | Indicates how the cast is performed. <b>f</b> means that the function specified in the <b>castfunc</b> field is used. <b>i</b> means that the input/output functions are used. <b>b</b> means that the types are binary-coercible, thus no conversion is required.                            |

The cast functions listed in **pg\_cast** must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type **integer**; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type **boolean**; it receives **true** if the cast is an explicit cast, **false** otherwise.

It is legitimate to create a **pg\_cast** entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a **pg\_cast** entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## 52.11. pg\_class

The catalog **pg\_class** describes tables and other objects that have columns or are otherwise similar to a table. This includes indexes (but see also **pg\_index**), sequences (but see also **pg\_sequence**), views, materialized views, composite types, and TOAST tables; see **relkind**. Below, when we mean all of these kinds of objects we speak of “relations”. Not all of **pg\_class**'s columns are meaningful for all relation kinds.

**Table 52.11. pg\_class Columns**

| Column Type                                    | Description                                          |
|------------------------------------------------|------------------------------------------------------|
| oid oid                                        | Row identifier                                       |
| relname name                                   | Name of the table, index, view, etc.                 |
| relnamespace oid (references pg_namespace.oid) | The OID of the namespace that contains this relation |

| Column Type                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>reltype oid</code> (references <code>pg_type.oid</code> )             | The OID of the data type that corresponds to this table's row type, if any; zero for indexes, sequences, and toast tables, which have no <code>pg_type</code> entry                                                                                                                                                                                                                        |
| <code>reloftype oid</code> (references <code>pg_type.oid</code> )           | For typed tables, the OID of the underlying composite type; zero for all other relations                                                                                                                                                                                                                                                                                                   |
| <code>relowner oid</code> (references <code>pg_authid.oid</code> )          | Owner of the relation                                                                                                                                                                                                                                                                                                                                                                      |
| <code>relam oid</code> (references <code>pg_am.oid</code> )                 | The access method used to access this table or index. Not meaningful if the relation is a sequence or has no on-disk file, except for partitioned tables, where, if set, it takes precedence over <code>default_table_access_method</code> when determining the access method to use for partitions created when one is not specified in the creation command.                             |
| <code>relfilenode oid</code>                                                | Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state                                                                                                                                                                                                                                                    |
| <code>reltablespace oid</code> (references <code>pg_tablespace.oid</code> ) | The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. Not meaningful if the relation has no on-disk file, except for partitioned tables, where this is the tablespace in which partitions will be created when one is not specified in the creation command.                                                                             |
| <code>relpages int4</code>                                                  | Size of the on-disk representation of this table in pages (of size <code>BLCKSZ</code> ). This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .                                                                                                                           |
| <code>reltuples float4</code>                                               | Number of live rows in the table. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> . If the table has never yet been vacuumed or analyzed, <code>reltuples</code> contains <code>-1</code> indicating that the row count is unknown.                                   |
| <code>relallvisible int4</code>                                             | Number of pages that are marked all-visible in the table's visibility map. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .                                                                                                                                          |
| <code>relallfrozen int4</code>                                              | Number of pages that are marked all-frozen in the table's visibility map. This is only an estimate used for triggering autovacuum. It can also be used along with <code>relallvisible</code> for scheduling manual vacuums and tuning vacuum's freezing behavior. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> . |
| <code>reltoastrelid oid</code> (references <code>pg_class.oid</code> )      | OID of the TOAST table associated with this table, zero if none. The TOAST table stores large attributes “out of line” in a secondary table.                                                                                                                                                                                                                                               |
| <code>relhasindex bool</code>                                               | True if this is a table and it has (or recently had) any indexes                                                                                                                                                                                                                                                                                                                           |
| <code>relisshared bool</code>                                               | True if this table is shared across all databases in the cluster. Only certain system catalogs (such as <code>pg_database</code> ) are shared.                                                                                                                                                                                                                                             |
| <code>relpersistence char</code>                                            | <code>p</code> = permanent table/sequence, <code>u</code> = unlogged table/sequence, <code>t</code> = temporary table/sequence                                                                                                                                                                                                                                                             |
| <code>relkind char</code>                                                   |                                                                                                                                                                                                                                                                                                                                                                                            |

| Column Type                                                         | Description                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     | <code>r</code> = ordinary table, <code>i</code> = index, <code>S</code> = sequence, <code>t</code> = TOAST table, <code>v</code> = view, <code>m</code> = materialized view, <code>C</code> = composite type, <code>f</code> = foreign table, <code>p</code> = partitioned table, <code>I</code> = partitioned index                                  |
| <code>relnatts int2</code>                                          | Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> . See also <code>pg_attribute.attnum</code> .                                                                                                                                                         |
| <code>relchecks int2</code>                                         | Number of CHECK constraints on the table; see <code>pg_constraint</code> catalog                                                                                                                                                                                                                                                                      |
| <code>relhasrules bool</code>                                       | True if table has (or once had) rules; see <code>pg_rewrite</code> catalog                                                                                                                                                                                                                                                                            |

| <code>relforcerowsecurity bool</code>                               | True if row-level security (when enabled) will also apply to table owner; see <code>pg_policy</code> catalog                                                                                                                                                                                                                                          |
| <code>relispopulated bool</code>                                    | True if relation is populated (this is true for all relations other than some materialized views)                                                                                                                                                                                                                                                     |
| <code>relreplident char</code>                                      | Columns used to form “replica identity” for rows: <code>d</code> = default (primary key, if any), <code>n</code> = nothing, <code>f</code> = all columns, <code>i</code> = index with <code>indisreplident</code> set (same as nothing if the index used has been dropped)                                                                            |
| <code>relispartition bool</code>                                    | True if table or index is a partition                                                                                                                                                                                                                                                                                                                 |
| <code>relrewrite oid</code> (references <code>pg_class.oid</code> ) | For new relations being written during a DDL operation that requires a table rewrite, this contains the OID of the original relation; otherwise zero. That state is only visible internally; this field should never contain anything other than zero for a user-visible relation.                                                                    |
| <code>relfrozenxid xid</code>                                       | All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk. Zero ( <code>InvalidTransactionId</code> ) if the relation is not a table. |
| <code>relminmxid xid</code>                                         | All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. Zero ( <code>InvalidMultiXactId</code> ) if the relation is not a table.                         |
| <code>relaclaclitem[]</code>                                        | Access privileges; see Section 5.8 for details                                                                                                                                                                                                                                                                                                        |
| <code>reloptions text[]</code>                                      | Access-method-specific options, as “keyword=value” strings                                                                                                                                                                                                                                                                                            |
| <code>relpartbound pg_node_tree</code>                              |                                                                                                                                                                                                                                                                                                                                                       |

| Column Type                                                                                                |
|------------------------------------------------------------------------------------------------------------|
| Description                                                                                                |
| If table is a partition (see <code>relispartition</code> ), internal representation of the partition bound |

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex` is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM` clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

## 52.12. pg\_collation

The catalog `pg_collation` describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 23.2 for more information.

Table 52.12. `pg_collation` Columns

| Column Type                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description                                                                                                                                                                                                                                           |
| <code>oid oid</code><br>Row identifier                                                                                                                                                                                                                |
| <code>collname name</code><br>Collation name (unique per namespace and encoding)                                                                                                                                                                      |
| <code>collnamespace oid</code> (references <code>pg_namespace.oid</code> )<br>The OID of the namespace that contains this collation                                                                                                                   |
| <code>collowner oid</code> (references <code>pg_authid.oid</code> )<br>Owner of the collation                                                                                                                                                         |
| <code>collprovider char</code><br>Provider of the collation: <code>d</code> = database default, <code>b</code> = builtin, <code>c</code> = libc, <code>i</code> = icu                                                                                 |
| <code>collisdeterministic bool</code><br>Is the collation deterministic?                                                                                                                                                                              |
| <code>collencoding int4</code><br>Encoding in which the collation is applicable, or -1 if it works for any encoding                                                                                                                                   |
| <code>collcollate text</code><br><code>LC_COLLATE</code> for this collation object. If the provider is not <code>libc</code> , <code>collcollate</code> is <code>NULL</code> and <code>colllocale</code> is used instead.                             |
| <code>collctype text</code><br><code>LC_CTYPE</code> for this collation object. If the provider is not <code>libc</code> , <code>collctype</code> is <code>NULL</code> and <code>colllocale</code> is used instead.                                   |
| <code>colllocale text</code><br>Collation provider locale name for this collation object. If the provider is <code>libc</code> , <code>colllocale</code> is <code>NULL</code> ; <code>collcollate</code> and <code>collctype</code> are used instead. |
| <code>collicurules text</code><br>ICU collation rules for this collation object                                                                                                                                                                       |
| <code>collversion text</code><br>Provider-specific version of the collation. This is recorded when the collation is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.       |

Note that the unique key on this catalog is (`collname`, `collencoding`, `collnamespace`) not just (`collname`, `collnamespace`). PostgreSQL generally ignores all collations that do not have

`collencoding` equal to either the current database's encoding or -1, and creation of new entries with the same name as an entry with `collencoding = -1` is forbidden. Therefore it is sufficient to use a qualified SQL name (*schema.name*) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that `initdb` fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the `template0` database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from `template0`. This would currently have to be done manually.

## 52.13. pg\_constraint

The catalog `pg_constraint` stores check, not-null, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.)

User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

**Table 52.13. pg\_constraint Columns**

| Column Type                                                               | Description                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                      | Row identifier                                                                                                                                                                                                                                                            |
| <code>conname name</code>                                                 | Constraint name (not necessarily unique!)                                                                                                                                                                                                                                 |

| <code>coninhcount int2</code>                                                     | The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.                                      |
| <code>connoinherit bool</code>                                                    | This constraint is defined locally for the relation. It is a non-inheritable constraint.                                                                                            |
| <code>conperiod bool</code>                                                       | This constraint is defined with <code>WITHOUT OVERLAPS</code> (for primary keys and unique constraints) or <code>PERIOD</code> (for foreign keys).                                  |
| <code>conkey int2[]</code> (references <code>pg_attribute.attnum</code> )         | If a table constraint (including foreign keys, but not constraint triggers), list of the constrained columns                                                                        |
| <code>confkey int2[]</code> (references <code>pg_attribute.attnum</code> )        | If a foreign key, list of the referenced columns                                                                                                                                    |
| <code>conpeqop oid[]</code> (references <code>pg_operator.oid</code> )            | If a foreign key, list of the equality operators for PK = FK comparisons                                                                                                            |
| <code>conppeqop oid[]</code> (references <code>pg_operator.oid</code> )           | If a foreign key, list of the equality operators for PK = PK comparisons                                                                                                            |
| <code>conffeqop oid[]</code> (references <code>pg_operator.oid</code> )           | If a foreign key, list of the equality operators for FK = FK comparisons                                                                                                            |
| <code>confdelsetcols int2[]</code> (references <code>pg_attribute.attnum</code> ) | If a foreign key with a <code>SET NULL</code> or <code>SET DEFAULT</code> delete action, the columns that will be updated. If null, all of the referencing columns will be updated. |
| <code>conexcllop oid[]</code> (references <code>pg_operator.oid</code> )          | If an exclusion constraint or <code>WITHOUT OVERLAPS</code> primary key/unique constraint, list of the per-column exclusion operators.                                              |
| <code>conbin pg_node_tree</code>                                                  | If a check constraint, an internal representation of the expression. (It's recommended to use <code>pg_get_constraintdef()</code> to extract the definition of a check constraint.) |

In the case of an exclusion constraint, `conkey` is only useful for constraint elements that are simple column references. For other cases, a zero appears in `conkey` and the associated index must be consulted to discover the expression that is constrained. (`conkey` thus has the same contents as `pg_index.indkey` for the index.)

**Note**

`pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

## 52.14. pg\_conversion

The catalog `pg_conversion` describes encoding conversion functions. See `CREATE CONVERSION` for more information.

**Table 52.14. pg\_conversion Columns**

| Column Type                                                               | Description                                                                                                  |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                      | Row identifier                                                                                               |
| <code>conname name</code>                                                 | Conversion name (unique within a namespace)                                                                  |
| <code>connamespace oid</code> (references <code>pg_namespace.oid</code> ) | The OID of the namespace that contains this conversion                                                       |
| <code>conowner oid</code> (references <code>pg_authid.oid</code> )        | Owner of the conversion                                                                                      |
| <code>conforencoding int4</code>                                          | Source encoding ID ( <code>pg_encoding_to_char()</code> can translate this number to the encoding name)      |
| <code>contoencoding int4</code>                                           | Destination encoding ID ( <code>pg_encoding_to_char()</code> can translate this number to the encoding name) |
| <code>conproc regproc</code> (references <code>pg_proc.oid</code> )       | Conversion function                                                                                          |
| <code>condefault bool</code>                                              | True if this is the default conversion                                                                       |

## 52.15. pg\_database

The catalog `pg_database` stores information about the available databases. Databases are created with the `CREATE DATABASE` command. Consult Chapter 22 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

**Table 52.15. pg\_database Columns**

| Column Type                                                      | Description                                            |
|------------------------------------------------------------------|--------------------------------------------------------|
| <code>oid oid</code>                                             | Row identifier                                         |
| <code>datname name</code>                                        | Database name                                          |
| <code>datdba oid</code> (references <code>pg_authid.oid</code> ) | Owner of the database, usually the user who created it |

| Column Type                                                                 | Description                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>encoding int4</code>                                                  | Character encoding for this database ( <code>pg_encoding_to_char()</code> can translate this number to the encoding name)                                                                                                                                                                                                                                      |
| <code>datloclprovider char</code>                                           | Locale provider for this database: <code>b</code> = builtin, <code>c</code> = libc, <code>i</code> = icu                                                                                                                                                                                                                                                       |
| <code>datistemplate bool</code>                                             | If true, then this database can be cloned by any user with <code>CREATEDB</code> privileges; if false, then only superusers or the owner of the database can clone it.                                                                                                                                                                                         |
| <code>dataallowconn bool</code>                                             | If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.                                                                                                                                                                                                                             |
| <code>dathasloginevt bool</code>                                            | Indicates that there are login event triggers defined for this database. This flag is used to avoid extra lookups on the <code>pg_event_trigger</code> table during each backend startup. This flag is used internally by PostgreSQL and should not be manually altered or read for monitoring purposes.                                                       |
| <code>datconnlimit int4</code>                                              | Sets maximum number of concurrent connections that can be made to this database. -1 means no limit, -2 indicates the database is invalid.                                                                                                                                                                                                                      |
| <code>datfrozenxid xid</code>                                               | All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relfrozenxid</code> values. |
| <code>datminmxid xid</code>                                                 | All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relminmxid</code> values.                       |
| <code>dattablespace oid</code> (references <code>pg_tablespace.oid</code> ) | The default tablespace for the database. Within this database, all tables for which <code>pg_class.reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.                                                                                                                            |
| <code>datcollate text</code>                                                | <code>LC_COLLATE</code> for this database                                                                                                                                                                                                                                                                                                                      |
| <code>datctype text</code>                                                  | <code>LC_CTYPE</code> for this database                                                                                                                                                                                                                                                                                                                        |
| <code>datlocale text</code>                                                 | Collation provider locale name for this database. If the provider is <code>libc</code> , <code>datlocale</code> is <code>NULL</code> ; <code>datcollate</code> and <code>datctype</code> are used instead.                                                                                                                                                     |
| <code>daticurules text</code>                                               | ICU collation rules for this database                                                                                                                                                                                                                                                                                                                          |
| <code>datcollversion text</code>                                            | Provider-specific version of the collation. This is recorded when the database is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.                                                                                                                                                  |
| <code>dataclaclitem[]</code>                                                | Access privileges; see Section 5.8 for details                                                                                                                                                                                                                                                                                                                 |

## 52.16. pg\_db\_role\_setting

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

**Table 52.16. pg\_db\_role\_setting Columns**

| Column Type                                                             | Description                                                                            |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <code>setdatabase oid</code> (references <code>pg_database.oid</code> ) | The OID of the database the setting is applicable to, or zero if not database-specific |
| <code>setrole oid</code> (references <code>pg_authid.oid</code> )       | The OID of the role the setting is applicable to, or zero if not role-specific         |
| <code>setconfig text[]</code>                                           | Defaults for run-time configuration variables                                          |

## 52.17. pg\_default\_acl

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

**Table 52.17. pg\_default\_acl Columns**

| Column Type                                                                  | Description                                                                                                                                                                                                    |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                         | Row identifier                                                                                                                                                                                                 |
| <code>defaclrole oid</code> (references <code>pg_authid.oid</code> )         | The OID of the role associated with this entry                                                                                                                                                                 |
| <code>defaclnamespace oid</code> (references <code>pg_namespace.oid</code> ) | The OID of the namespace associated with this entry, or zero if none                                                                                                                                           |
| <code>defaclobjtype char</code>                                              | Type of object this entry is for: <code>r</code> = relation (table, view), <code>S</code> = sequence, <code>f</code> = function, <code>T</code> = type, <code>n</code> = schema, <code>L</code> = large object |
| <code>defaclacl aclitem[]</code>                                             | Access privileges that this type of object should have on creation                                                                                                                                             |

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace` = zero, and “per-schema” entries that reference a particular schema. If a global entry is present then it *overrides* the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be *added* to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, *not* whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

## 52.18. pg\_depend

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

**Table 52.18. `pg_depend` Columns**

| Column Type                                                         | Description                                                                                                                                                                       |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>classid oid</code> (references <code>pg_class.oid</code> )    | The OID of the system catalog the dependent object is in                                                                                                                          |
| <code>objid oid</code> (references any OID column)                  | The OID of the specific dependent object                                                                                                                                          |
| <code>objsubid int4</code>                                          | For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.       |
| <code>refclassid oid</code> (references <code>pg_class.oid</code> ) | The OID of the system catalog the referenced object is in                                                                                                                         |
| <code>refobjid oid</code> (references any OID column)               | The OID of the specific referenced object                                                                                                                                         |
| <code>refobjsubid int4</code>                                       | For a table column, this is the column number (the <code>refobjid</code> and <code>refclassid</code> refer to the table itself). For all other object types, this column is zero. |
| <code>deptype char</code>                                           | A code defining the specific semantics of this dependency relationship; see text                                                                                                  |

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

#### DEPENDENCY\_NORMAL (n)

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

#### DEPENDENCY\_AUTO (a)

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made auto-dependent on the table, so that it will go away if the table is dropped.

#### DEPENDENCY\_INTERNAL (i)

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A direct `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will result in automatically dropping the dependent object whether `CASCADE` is specified or not. If the dependent object has to be dropped due to a dependency on some other object being removed, its drop is converted to a drop of the referenced object, so that `NORMAL` and `AUTO` dependencies of the dependent object behave much like they were dependencies of the referenced object. Example: a view's `ON SELECT` rule is made internally dependent on the view, preventing it from being dropped while the view remains. Dependencies of the rule (such as tables it refers to) act as if they were dependencies of the view.

**DEPENDENCY\_PARTITION\_PRI (P)****DEPENDENCY\_PARTITION\_SEC (S)**

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation; however, unlike **INTERNAL**, there is more than one such referenced object. The dependent object must not be dropped unless at least one of these referenced objects is dropped; if any one is, the dependent object should be dropped whether or not **CASCADE** is specified. Also unlike **INTERNAL**, a drop of some other object that the dependent object depends on does not result in automatic deletion of any partition-referenced object. Hence, if the drop does not cascade to at least one of these objects via some other path, it will be refused. (In most cases, the dependent object shares all its non-partition dependencies with at least one partition-referenced object, so that this restriction does not result in blocking any cascaded delete.) Primary and secondary partition dependencies behave identically except that the primary dependency is preferred for use in error messages; hence, a partition-dependent object should have one primary partition dependency and one or more secondary partition dependencies. Note that partition dependencies are made in addition to, not instead of, any dependencies the object would normally have. This simplifies **ATTACH/DETACH PARTITION** operations: the partition dependencies need only be added or removed. Example: a child partitioned index is made partition-dependent on both the partition table it is on and the parent partitioned index, so that it goes away if either of those is dropped, but not otherwise. The dependency on the parent index is primary, so that if the user tries to drop the child partitioned index, the error message will suggest dropping the parent index instead (not the table).

**DEPENDENCY\_EXTENSION (e)**

The dependent object is a member of the *extension* that is the referenced object (see `pg_extension`). The dependent object can be dropped only via **DROP EXTENSION** on the referenced object. Functionally this dependency type acts the same as an **INTERNAL** dependency, but it's kept separate for clarity and to simplify `pg_dump`.

**DEPENDENCY\_AUTO\_EXTENSION (x)**

The dependent object is not a member of the extension that is the referenced object (and so it should not be ignored by `pg_dump`), but it cannot function without the extension and should be auto-dropped if the extension is. The dependent object may be dropped on its own as well. Functionally this dependency type acts the same as an **AUTO** dependency, but it's kept separate for clarity and to simplify `pg_dump`.

Other dependency flavors might be needed in future.

Note that it's quite possible for two objects to be linked by more than one `pg_depend` entry. For example, a child partitioned index would have both a partition-type dependency on its associated partition table, and an auto dependency on each column of that table that it indexes. This sort of situation expresses the union of multiple dependency semantics. A dependent object can be dropped without **CASCADE** if any of its dependencies satisfies its condition for automatic dropping. Conversely, all the dependencies' restrictions about which objects must be dropped together must be satisfied.

Most objects created during `initdb` are considered “pinned”, which means that the system itself depends on them. Therefore, they are never allowed to be dropped. Also, knowing that pinned objects will not be dropped, the dependency mechanism doesn't bother to make `pg_depend` entries showing dependencies on them. Thus, for example, a table column of type `numeric` notionally has a **NORMAL** dependency on the `numeric` data type, but no such entry actually appears in `pg_depend`.

## 52.19. `pg_description`

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the **COMMENT** command and viewed with `psql's \d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

**Table 52.19. `pg_description` Columns**

| Column Type                   | Description                                                                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>objoid oid</code>       | (references any OID column)<br>The OID of the object this description pertains to                                                                                                          |
| <code>classoid oid</code>     | (references <code>pg_class.oid</code> )<br>The OID of the system catalog this object appears in                                                                                            |
| <code>objsubid int4</code>    | For a comment on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero. |
| <code>description text</code> | Arbitrary text that serves as the description of this object                                                                                                                               |

## 52.20. `pg_enum`

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

**Table 52.20. `pg_enum` Columns**

| Column Type                       | Description                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>              | Row identifier                                                                                             |
| <code>enumtypid oid</code>        | (references <code>pg_type.oid</code> )<br>The OID of the <code>pg_type</code> entry owning this enum value |
| <code>enumsortorder float4</code> | The sort position of this enum value within its enum type                                                  |
| <code>enumlabel name</code>       | The textual label for this enum value                                                                      |

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions  $1..n$ . But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

## 52.21. `pg_event_trigger`

The catalog `pg_event_trigger` stores event triggers. See Chapter 38 for more information.

**Table 52.21. `pg_event_trigger` Columns**

| Column Type          | Description |
|----------------------|-------------|
| <code>oid oid</code> |             |

| Column Type                             | Description                                                                                                                                                                                                        |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | Row identifier                                                                                                                                                                                                     |
| evtname name                            | Trigger name (must be unique)                                                                                                                                                                                      |
| evtevent name                           | Identifies the event for which this trigger fires                                                                                                                                                                  |
| evtowner oid (references pg_authid.oid) | Owner of the event trigger                                                                                                                                                                                         |
| evtfoid oid (references pg_proc.oid)    | The function to be called                                                                                                                                                                                          |
| evenabled char                          | Controls in which session_replication_role modes the event trigger fires. O = trigger fires in “origin” and “local” modes, D = trigger is disabled, R = trigger fires in “replica” mode, A = trigger fires always. |
| evttags text[]                          | Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.                                                                              |

## 52.22. pg\_extension

The catalog `pg_extension` stores information about the installed extensions. See Section 36.17 for details about extensions.

**Table 52.22. pg\_extension Columns**

| Column Type                                    | Description                                                                                         |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| oid oid                                        | Row identifier                                                                                      |
| extname name                                   | Name of the extension                                                                               |
| extowner oid (references pg_authid.oid)        | Owner of the extension                                                                              |
| extnamespace oid (references pg_namespace.oid) | Schema containing the extension's exported objects                                                  |
| extrelocatable bool                            | True if extension can be relocated to another schema                                                |
| extversion text                                | Version name for the extension                                                                      |
| extconfig oid[] (references pg_class.oid)      | Array of regclass OIDs for the extension's configuration table(s), or NULL if none                  |
| extcondition text[]                            | Array of WHERE-clause filter conditions for the extension's configuration table(s), or NULL if none |

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension's objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

## 52.23. pg\_foreign\_data\_wrapper

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

**Table 52.23. pg\_foreign\_data\_wrapper Columns**

| Column Type                                            | Description                                                                                                                                                                                                                                               |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                   | Row identifier                                                                                                                                                                                                                                            |
| <code>fdwname name</code>                              | Name of the foreign-data wrapper                                                                                                                                                                                                                          |
| <code>fdwowner oid (references pg_authid.oid)</code>   | Owner of the foreign-data wrapper                                                                                                                                                                                                                         |
| <code>fdwhandler oid (references pg_proc.oid)</code>   | References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided                                                                                                           |
| <code>fdwvalidator oid (references pg_proc.oid)</code> | References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided |
| <code>fdwaccl aclitem[]</code>                         | Access privileges; see Section 5.8 for details                                                                                                                                                                                                            |
| <code>fdwoptions text[]</code>                         | Foreign-data wrapper specific options, as “keyword=value” strings                                                                                                                                                                                         |

## 52.24. pg\_foreign\_server

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

**Table 52.24. pg\_foreign\_server Columns**

| Column Type                                                      | Description                                            |
|------------------------------------------------------------------|--------------------------------------------------------|
| <code>oid oid</code>                                             | Row identifier                                         |
| <code>srvname name</code>                                        | Name of the foreign server                             |
| <code>srvowner oid (references pg_authid.oid)</code>             | Owner of the foreign server                            |
| <code>srvfdw oid (references pg_foreign_data_wrapper.oid)</code> | OID of the foreign-data wrapper of this foreign server |
| <code>srvtype text</code>                                        | Type of the server (optional)                          |
| <code>srvversion text</code>                                     | Version of the server (optional)                       |
| <code>srvaccl aclitem[]</code>                                   | Access privileges; see Section 5.8 for details         |
| <code>srvoptions text[]</code>                                   |                                                        |

| Column Type                                                 |
|-------------------------------------------------------------|
| Description                                                 |
| Foreign server specific options, as “keyword=value” strings |

## 52.25. pg\_foreign\_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

**Table 52.25. pg\_foreign\_table Columns**

| Column Type                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------|
| Description                                                                                                                           |

## 52.26. pg\_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

**Table 52.26. pg\_index Columns**

| Column Type                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description                                                                                                                                                                                                                                                                                                                                                           |
| <code>indexrelid oid</code> (references <code>pg_class.oid</code> )<br>The OID of the <code>pg_class</code> entry for this index                                                                                                                                                                                                                                      |
| <code>indrelid oid</code> (references <code>pg_class.oid</code> )<br>The OID of the <code>pg_class</code> entry for the table this index is for                                                                                                                                                                                                                       |
| <code>indnatts int2</code><br>The total number of columns in the index (duplicates <code>pg_class.relnatts</code> ); this number includes both key and included attributes                                                                                                                                                                                            |
| <code>indnkeyatts int2</code><br>The number of <i>key columns</i> in the index, not counting any <i>included columns</i> , which are merely stored and do not participate in the index semantics                                                                                                                                                                      |
| <code>indisunique bool</code><br>If true, this is a unique index                                                                                                                                                                                                                                                                                                      |
| <code>indnullsnotdistinct bool</code><br>This value is only used for unique indexes. If false, this unique index will consider null values distinct (so the index can contain multiple null values in a column, the default PostgreSQL behavior). If it is true, it will consider null values to be equal (so the index can only contain one null value in a column). |
| <code>indisprimary bool</code><br>If true, this index represents the primary key of the table ( <code>indisunique</code> should always be true when this is true)                                                                                                                                                                                                     |
| <code>indisexclusion bool</code><br>If true, this index supports an exclusion constraint                                                                                                                                                                                                                                                                              |

| Column Type                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>indimmediate</code> bool                                                  | If true, the uniqueness check is enforced immediately on insertion (irrelevant if <code>indisunique</code> is not true)                                                                                                                                                                                                                                                                                                       |
| <code>indisclustered</code> bool                                                | If true, the table was last clustered on this index                                                                                                                                                                                                                                                                                                                                                                           |
| <code>indisvalid</code> bool                                                    | If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.                                                                                                                                        |
| <code>indcheckxmin</code> bool                                                  | If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because the table may contain broken HOT chains with incompatible rows that they can see                                                                                                                                                                     |
| <code>indisready</code> bool                                                    | If true, the index is currently ready for inserts. False means the index must be ignored by <code>INSERT/UPDATE</code> operations.                                                                                                                                                                                                                                                                                            |
| <code>indislive</code> bool                                                     | If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)                                                                                                                                                                                                                                                                                                   |
| <code>indisreplident</code> bool                                                | If true this index has been chosen as “replica identity” using <code>ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</code>                                                                                                                                                                                                                                                                                                  |
| <code>indkey</code> int2vector (references <code>pg_attribute.attnum</code> )   | This is an array of <code>indnatts</code> values that indicate which table columns this index indexes. For example, a value of 1 3 would mean that the first and the third table columns make up the index entries. Key columns come before non-key (included) columns. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference. |
| <code>indcollation</code> oidvector (references <code>pg_collation.oid</code> ) | For each column in the index key ( <code>indnkeyatts</code> values), this contains the OID of the collation to use for the index, or zero if the column is not of a collatable data type.                                                                                                                                                                                                                                     |
| <code>indclass</code> oidvector (references <code>pg_opclass.oid</code> )       | For each column in the index key ( <code>indnkeyatts</code> values), this contains the OID of the operator class to use. See <code>pg_opclass</code> for details.                                                                                                                                                                                                                                                             |
| <code>indoption</code> int2vector                                               | This is an array of <code>indnkeyatts</code> values that store per-column flag bits. The meaning of the bits is defined by the index's access method.                                                                                                                                                                                                                                                                         |
| <code>indexprs</code> pg_node_tree                                              | Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code> . Null if all index attributes are simple references.                                                                                                                                                                 |
| <code>indpred</code> pg_node_tree                                               | Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. Null if not a partial index.                                                                                                                                                                                                                                                                                                     |

## 52.27. pg\_inherits

The catalog `pg_inherits` records information about table and index inheritance hierarchies. There is one entry for each direct parent-child table or index relationship in the database. (Indirect inheritance can be determined by following chains of entries.)

**Table 52.27. pg\_inherits Columns**

| Column Type                                                        | Description                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inhrelid oid</code> (references <code>pg_class.oid</code> )  | The OID of the child table or index                                                                                                                                                                                                                                                                |
| <code>inhparent oid</code> (references <code>pg_class.oid</code> ) | The OID of the parent table or index                                                                                                                                                                                                                                                               |
| <code>inhseqno int4</code>                                         | If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1. Indexes cannot have multiple inheritance, since they can only inherit when using declarative partitioning. |
| <code>inhdetachpending bool</code>                                 | <code>true</code> for a partition that is in the process of being detached; <code>false</code> otherwise.                                                                                                                                                                                          |

## 52.28. pg\_init\_privs

The catalog `pg_init_privs` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by `initdb`) or when the object is created during a `CREATE EXTENSION` and the extension script sets initial privileges using the `GRANT` system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the `GRANT` and `REVOKE` statements in their script to have the privileges recorded. The `privtype` column indicates if the initial privilege was set by `initdb` or during a `CREATE EXTENSION` command.

Objects which have initial privileges set by `initdb` will have entries where `privtype` is `'i'`, while objects which have initial privileges set by `CREATE EXTENSION` will have entries where `privtype` is `'e'`.

**Table 52.28. pg\_init\_privs Columns**

| Column Type                                                       | Description                                                                                                                                                                   |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>objoid oid</code> (references any OID column)               | The OID of the specific object                                                                                                                                                |
| <code>classoid oid</code> (references <code>pg_class.oid</code> ) | The OID of the system catalog the object is in                                                                                                                                |
| <code>objsubid int4</code>                                        | For a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero. |
| <code>privtype char</code>                                        | A code defining the type of initial privilege of this object; see text                                                                                                        |
| <code>initprivs aclitem[]</code>                                  | The initial access privileges; see Section 5.8 for details                                                                                                                    |

## 52.29. pg\_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See `CREATE LANGUAGE` and Chapter 40 for more information about language handlers.

**Table 52.29. pg\_language Columns**

| Column Type                                | Description                                                                                                                                                                                                                                   |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid oid                                    | Row identifier                                                                                                                                                                                                                                |
| lanname name                               | Name of the language                                                                                                                                                                                                                          |
| lanowner oid (references pg_authid.oid)    | Owner of the language                                                                                                                                                                                                                         |
| lanispl bool                               | This is false for internal languages (such as SQL) and true for user-defined languages. Currently, pg_dump still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future. |
| lanpltrusted bool                          | True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.                                |
| lanplcallfoid oid (references pg_proc.oid) | For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language. Zero for internal languages.                         |
| laninline oid (references pg_proc.oid)     | This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.                                                                                             |
| lanvalidator oid (references pg_proc.oid)  | This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.                                                              |
| lanacl aclitem[]                           | Access privileges; see Section 5.8 for details                                                                                                                                                                                                |

## 52.30. pg\_largeobject

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

**Table 52.30. pg\_largeobject Columns**

| Column Type                                       | Description                                                           |
|---------------------------------------------------|-----------------------------------------------------------------------|
| loid oid (references pg_largeobject_metadata.oid) | Identifier of the large object that includes this page                |
| pageno int4                                       | Page number of this page within its large object (counting from zero) |
| data bytea                                        |                                                                       |

| Column Type                                                                                             |
|---------------------------------------------------------------------------------------------------------|
| Description                                                                                             |
| Actual data stored in the large object. This will never be more than LOBLKSIZE bytes and might be less. |

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

## 52.31. `pg_largeobject_metadata`

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

Table 52.31. `pg_largeobject_metadata` Columns

| Column Type                                                                                     |
|-------------------------------------------------------------------------------------------------|
| Description                                                                                     |
| <code>oid oid</code><br>Row identifier                                                          |
| <code>lomowner oid</code> (references <code>pg_authid.oid</code> )<br>Owner of the large object |
| <code>lomacl aclitem[]</code><br>Access privileges; see Section 5.8 for details                 |

## 52.32. `pg_namespace`

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

Table 52.32. `pg_namespace` Columns

| Column Type                                                                                  |
|----------------------------------------------------------------------------------------------|
| Description                                                                                  |
| <code>oid oid</code><br>Row identifier                                                       |
| <code>nspname name</code><br>Name of the namespace                                           |
| <code>nspowner oid</code> (references <code>pg_authid.oid</code> )<br>Owner of the namespace |
| <code>nspacl aclitem[]</code><br>Access privileges; see Section 5.8 for details              |

## 52.33. `pg_opclass`

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their left-hand input.

Operator classes are described at length in Section 36.16.

**Table 52.33. pg\_opclass Columns**

| Column Type                                    | Description                                                |
|------------------------------------------------|------------------------------------------------------------|
| oid oid                                        | Row identifier                                             |
| opcmethod oid (references pg_am.oid)           | Index access method operator class is for                  |
| opcname name                                   | Name of this operator class                                |
| opcnamespace oid (references pg_namespace.oid) | Namespace of this operator class                           |
| opcowner oid (references pg_authid.oid)        | Owner of the operator class                                |
| opcfamily oid (references pg_opfamily.oid)     | Operator family containing the operator class              |
| opcintype oid (references pg_type.oid)         | Data type that the operator class indexes                  |
| opcdefault bool                                | True if this operator class is the default for opcintype   |
| opckeytype oid (references pg_type.oid)        | Type of data stored in index, or zero if same as opcintype |

An operator class's `opcmethod` must match the `opfmeth` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

## 52.34. pg\_operator

The catalog `pg_operator` stores information about operators. See `CREATE OPERATOR` and Section 36.14 for more information.

**Table 52.34. pg\_operator Columns**

| Column Type                                    | Description                                                  |
|------------------------------------------------|--------------------------------------------------------------|
| oid oid                                        | Row identifier                                               |
| oprname name                                   | Name of the operator                                         |
| oprnamespace oid (references pg_namespace.oid) | The OID of the namespace that contains this operator         |
| oprowner oid (references pg_authid.oid)        | Owner of the operator                                        |
| oprkind char                                   | b = infix operator (“both”), or l = prefix operator (“left”) |
| oprcanmerge bool                               | This operator supports merge joins                           |
| oprcanhash bool                                | This operator supports hash joins                            |
| oprleft oid (references pg_type.oid)           |                                                              |

| Column Type                                                           | Description                                                                          |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------|
|                                                                       | Type of the left operand (zero for a prefix operator)                                |
| <code>oprright oid</code> (references <code>pg_type.oid</code> )      | Type of the right operand                                                            |
| <code>oprresult oid</code> (references <code>pg_type.oid</code> )     | Type of the result (zero for a not-yet-defined “shell” operator)                     |
| <code>oprcom oid</code> (references <code>pg_operator.oid</code> )    | Commutator of this operator (zero if none)                                           |
| <code>oprnegate oid</code> (references <code>pg_operator.oid</code> ) | Negator of this operator (zero if none)                                              |
| <code>oprcode regproc</code> (references <code>pg_proc.oid</code> )   | Function that implements this operator (zero for a not-yet-defined “shell” operator) |
| <code>oprrest regproc</code> (references <code>pg_proc.oid</code> )   | Restriction selectivity estimation function for this operator (zero if none)         |
| <code>oprjoin regproc</code> (references <code>pg_proc.oid</code> )   | Join selectivity estimation function for this operator (zero if none)                |

## 52.35. `pg_opfamily`

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 36.16.

**Table 52.35. `pg_opfamily` Columns**

| Column Type                                                               | Description                                |
|---------------------------------------------------------------------------|--------------------------------------------|
| <code>oid oid</code>                                                      | Row identifier                             |
| <code>opfmeth oid</code> (references <code>pg_am.oid</code> )             | Index access method operator family is for |
| <code>opfname name</code>                                                 | Name of this operator family               |
| <code>opfnamespace oid</code> (references <code>pg_namespace.oid</code> ) | Namespace of this operator family          |
| <code>opfowner oid</code> (references <code>pg_authid.oid</code> )        | Owner of the operator family               |

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

## 52.36. `pg_parameter_acl`

The catalog `pg_parameter_acl` records configuration parameters for which privileges have been granted to one or more roles. No entry is made for parameters that have default privileges.

Unlike most system catalogs, `pg_parameter_acl` is shared across all databases of a cluster: there is only one copy of `pg_parameter_acl` per cluster, not one per database.

**Table 52.36. pg\_parameter\_acl Columns**

| Column Type     | Description                                                            |
|-----------------|------------------------------------------------------------------------|
| oid oid         | Row identifier                                                         |
| parname text    | The name of a configuration parameter for which privileges are granted |
| paraclaclitem[] | Access privileges; see Section 5.8 for details                         |

## 52.37. pg\_partitioned\_table

The catalog `pg_partitioned_table` stores information about how tables are partitioned.

**Table 52.37. pg\_partitioned\_table Columns**

| Column Type                                                         | Description                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| partrelid oid (references <code>pg_class.oid</code> )               | The OID of the <code>pg_class</code> entry for this partitioned table                                                                                                                                                                                                                                                                                                            |
| partstrat char                                                      | Partitioning strategy; <code>h</code> = hash partitioned table, <code>l</code> = list partitioned table, <code>r</code> = range partitioned table                                                                                                                                                                                                                                |
| partnatts int2                                                      | The number of columns in the partition key                                                                                                                                                                                                                                                                                                                                       |
| partdefid oid (references <code>pg_class.oid</code> )               | The OID of the <code>pg_class</code> entry for the default partition of this partitioned table, or zero if this partitioned table does not have a default partition                                                                                                                                                                                                              |
| partattrs int2vector (references <code>pg_attribute.attnum</code> ) | This is an array of <code>partnatts</code> values that indicate which table columns are part of the partition key. For example, a value of <code>1 3</code> would mean that the first and the third table columns make up the partition key. A zero in this array indicates that the corresponding partition key column is an expression, rather than a simple column reference. |
| partclass oidvector (references <code>pg_opclass.oid</code> )       | For each column in the partition key, this contains the OID of the operator class to use. See <code>pg_opclass</code> for details.                                                                                                                                                                                                                                               |
| partcollation oidvector (references <code>pg_collation.oid</code> ) | For each column in the partition key, this contains the OID of the collation to use for partitioning, or zero if the column is not of a collatable data type.                                                                                                                                                                                                                    |
| partexprs pg_node_tree                                              | Expression trees (in <code>nodeToString()</code> representation) for partition key columns that are not simple column references. This is a list with one element for each zero entry in <code>partattrs</code> . Null if all partition key columns are simple references.                                                                                                       |

## 52.38. pg\_policy

The catalog `pg_policy` stores row-level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

**Table 52.38. pg\_policy Columns**

| Column Type                               | Description                                                                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid oid                                   | Row identifier                                                                                                                                           |
| polname name                              | The name of the policy                                                                                                                                   |
| polrelid oid (references pg_class.oid)    | The table to which the policy applies                                                                                                                    |
| polcmd char                               | The command type to which the policy is applied: <b>r</b> for SELECT, <b>a</b> for INSERT, <b>w</b> for UPDATE, <b>d</b> for DELETE, or <b>*</b> for all |
| polpermissive bool                        | Is the policy permissive or restrictive?                                                                                                                 |
| polroles oid[] (references pg_authid.oid) | The roles to which the policy is applied; zero means <b>PUBLIC</b> (and normally appears alone in the array)                                             |
| polqual pg_node_tree                      | The expression tree to be added to the security barrier qualifications for queries that use the table                                                    |
| polwithcheck pg_node_tree                 | The expression tree to be added to the <b>WITH CHECK</b> qualifications for queries that attempt to add rows to the table                                |

**Note**

Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

## 52.39. pg\_proc

The catalog `pg_proc` stores information about functions, procedures, aggregate functions, and window functions (collectively also known as routines). See `CREATE FUNCTION`, `CREATE PROCEDURE`, and Section 36.3 for more information.

If `prokind` indicates that the entry is for an aggregate function, there should be a matching row in `pg_aggregate`.

**Table 52.39. pg\_proc Columns**

| Column Type                                    | Description                                          |
|------------------------------------------------|------------------------------------------------------|
| oid oid                                        | Row identifier                                       |
| proname name                                   | Name of the function                                 |
| pronamespace oid (references pg_namespace.oid) | The OID of the namespace that contains this function |
| proowner oid (references pg_authid.oid)        | Owner of the function                                |
| prolang oid (references pg_language.oid)       |                                                      |

| Column Type                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     | Implementation language or call interface of this function                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>procost float4</b>                                               | Estimated execution cost (in units of <code>cpu_operator_cost</code> ); if <b>prorerset</b> , this is cost per row returned                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>prorows float4</b>                                               | Estimated number of result rows (zero if not <b>prorerset</b> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>provariadic oid</b> (references <code>pg_type.oid</code> )       | Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>prosupport regproc</b> (references <code>pg_proc.oid</code> )    | Planner support function for this function (see Section 36.11), or zero if none                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>prokind char</b>                                                 | <b>f</b> for a normal function, <b>p</b> for a procedure, <b>a</b> for an aggregate function, or <b>w</b> for a window function                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>prosecdef bool</b>                                               | Function is a security definer (i.e., a “setuid” function)                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>proleakproof bool</b>                                            | The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leakproof.                                                                                                                                                                                                                                                                                                                |
| <b>proisstrict bool</b>                                             | Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.                                                                                                                                                                                                                                                                                                                                         |
| <b>prorerset bool</b>                                               | Function returns a set (i.e., multiple values of the specified data type)                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>provolatile char</b>                                             | <b>provolatile</b> tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is <b>i</b> for “immutable” functions, which always deliver the same result for the same inputs. It is <b>s</b> for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is <b>v</b> for “volatile” functions, whose results might change at any time. (Use <b>v</b> also for functions with side-effects, so that calls to them cannot get optimized away.) |
| <b>proparallel char</b>                                             | <b>proparallel</b> tells whether the function can be safely run in parallel mode. It is <b>s</b> for functions which are safe to run in parallel mode without restriction. It is <b>r</b> for functions which can be run in parallel mode, but their execution is restricted to the parallel group leader; parallel worker processes cannot invoke these functions. It is <b>u</b> for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.                            |
| <b>pronargs int2</b>                                                | Number of input arguments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>pronargdefaults int2</b>                                         | Number of arguments that have defaults                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>prorettype oid</b> (references <code>pg_type.oid</code> )        | Data type of the return value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>proargtypes oidvector</b> (references <code>pg_type.oid</code> ) | An array of the data types of the function arguments. This includes only input arguments (including <b>INOUT</b> and <b>VARIADIC</b> arguments), and thus represents the call signature of the function.                                                                                                                                                                                                                                                                                                                       |

| Column Type                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>proallargtypes oid[]</code> (references <code>pg_type.oid</code> ) | An array of the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0.                                                                                                        |
| <code>proargmodes char[]</code>                                          | An array of the modes of the function arguments, encoded as <code>i</code> for IN arguments, <code>o</code> for OUT arguments, <code>b</code> for INOUT arguments, <code>v</code> for VARIADIC arguments, <code>t</code> for TABLE arguments. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> . |
| <code>proargnames text[]</code>                                          | An array of the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .                                                                                                                               |
| <code>proargdefaults pg_node_tree</code>                                 | Expression trees (in <code>nodeToString()</code> representation) for default values. This is a list with <code>pronargdefaults</code> elements, corresponding to the last <i>N</i> input arguments (i.e., the last <i>N</i> <code>proargtypes</code> positions). If none of the arguments have defaults, this field will be null.                                                                                        |
| <code>protrftypes oid[]</code> (references <code>pg_type.oid</code> )    | An array of the argument/result data type(s) for which to apply transforms (from the function's TRANSFORM clause). Null if none.                                                                                                                                                                                                                                                                                         |
| <code>prosrc text</code>                                                 | This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.                                                                                                                                                             |
| <code>probin text</code>                                                 | Additional information about how to invoke the function. Again, the interpretation is language-specific.                                                                                                                                                                                                                                                                                                                 |
| <code>prosqlbody pg_node_tree</code>                                     | Pre-parsed SQL function body. This is used for SQL-language functions when the body is given in SQL-standard notation rather than as a string literal. It's null in other cases.                                                                                                                                                                                                                                         |
| <code>proconfig text[]</code>                                            | Function's local settings for run-time configuration variables                                                                                                                                                                                                                                                                                                                                                           |
| <code>proaclaclitem[]</code>                                             | Access privileges; see Section 5.8 for details                                                                                                                                                                                                                                                                                                                                                                           |

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For SQL-language functions, `prosrc` contains the function's source text if that is specified as a string literal; but if the function body is specified in SQL-standard style, `prosrc` is unused (typically it's an empty string) and `prosqlbody` contains the pre-parsed definition. For all other currently-known language types, `prosrc` contains the function's source text. `probin` is null except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

## 52.40. pg\_publication

The catalog `pg_publication` contains all publications created in the database. For more on publications see Section 29.1.

**Table 52.40. pg\_publication Columns**

| Column Type                             | Description                                                                                                                                                                                                                                                                                  |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid oid                                 | Row identifier                                                                                                                                                                                                                                                                               |
| pubname name                            | Name of the publication                                                                                                                                                                                                                                                                      |
| pubowner oid (references pg_authid.oid) | Owner of the publication                                                                                                                                                                                                                                                                     |
| puballtables bool                       | If true, this publication automatically includes all tables in the database, including any that will be created in the future.                                                                                                                                                               |
| pubinsert bool                          | If true, INSERT operations are replicated for tables in the publication.                                                                                                                                                                                                                     |
| pubupdate bool                          | If true, UPDATE operations are replicated for tables in the publication.                                                                                                                                                                                                                     |
| pubdelete bool                          | If true, DELETE operations are replicated for tables in the publication.                                                                                                                                                                                                                     |
| pubtruncate bool                        | If true, TRUNCATE operations are replicated for tables in the publication.                                                                                                                                                                                                                   |
| pubviaroot bool                         | If true, operations on a leaf partition are replicated using the identity and schema of its topmost partitioned ancestor mentioned in the publication instead of its own.                                                                                                                    |
| pubgencols char                         | Controls how to handle generated column replication when there is no publication column list: n = generated columns in the tables associated with the publication should not be replicated, s = stored generated columns in the tables associated with the publication should be replicated. |

## 52.41. pg\_publication\_namespace

The catalog `pg_publication_namespace` contains the mapping between schemas and publications in the database. This is a many-to-many mapping.

**Table 52.41. pg\_publication\_namespace Columns**

| Column Type                                 | Description              |
|---------------------------------------------|--------------------------|
| oid oid                                     | Row identifier           |
| pnpubid oid (references pg_publication.oid) | Reference to publication |
| pnnspid oid (references pg_namespace.oid)   | Reference to schema      |

## 52.42. pg\_publication\_rel

The catalog `pg_publication_rel` contains the mapping between relations and publications in the database. This is a many-to-many mapping. See also Section 53.18 for a more user-friendly view of this information.

**Table 52.42. pg\_publication\_rel Columns**

| Column Type                                         | Description                                                                                                                                                                                                                                                     |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| oid oid                                             | Row identifier                                                                                                                                                                                                                                                  |
| prpubid oid (references pg_publication.oid)         | Reference to publication                                                                                                                                                                                                                                        |
| prrelid oid (references pg_class.oid)               | Reference to relation                                                                                                                                                                                                                                           |
| prqual pg_node_tree                                 | Expression tree (in <code>nodeToString()</code> representation) for the relation's publication qualifying condition. Null if there is no publication qualifying condition.                                                                                      |
| prattrs int2vector (references pg_attribute.attnum) | This is an array of values that indicates which table columns are part of the publication. For example, a value of <code>1 3</code> would mean that the first and the third table columns are published. A null value indicates that all columns are published. |

## 52.43. pg\_range

The catalog `pg_range` stores information about range types. This is in addition to the types' entries in `pg_type`.

**Table 52.43. pg\_range Columns**

| Column Type                                    | Description                                                                                                  |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| rngtypid oid (references pg_type.oid)          | OID of the range type                                                                                        |
| rngsubtype oid (references pg_type.oid)        | OID of the element type (subtype) of this range type                                                         |
| rngmultitypid oid (references pg_type.oid)     | OID of the multirange type for this range type                                                               |
| rngcollation oid (references pg_collation.oid) | OID of the collation used for range comparisons, or zero if none                                             |
| rngsubopc oid (references pg_opclass.oid)      | OID of the subtype's operator class used for range comparisons                                               |
| rngcanonical regproc (references pg_proc.oid)  | OID of the function to convert a range value into canonical form, or zero if none                            |
| rngsubdiff regproc (references pg_proc.oid)    | OID of the function to return the difference between two element values as double precision, or zero if none |

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

## 52.44. pg\_replication\_origin

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see Chapter 48.

Unlike most system catalogs, `pg_replication_origin` is shared across all databases of a cluster: there is only one copy of `pg_replication_origin` per cluster, not one per database.

**Table 52.44. `pg_replication_origin` Columns**

| Column Type              | Description                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------|
| <code>roident oid</code> | A unique, cluster-wide identifier for the replication origin. Should never leave the system. |
| <code>roname text</code> | The external, user defined, name of a replication origin.                                    |

## 52.45. `pg_rewrite`

The catalog `pg_rewrite` stores rewrite rules for tables and views.

**Table 52.45. `pg_rewrite` Columns**

| Column Type                                                       | Description                                                                                                                                                                                   |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                              | Row identifier                                                                                                                                                                                |
| <code>rulename name</code>                                        | Rule name                                                                                                                                                                                     |
| <code>ev_class oid</code> (references <code>pg_class.oid</code> ) | The table this rule is for                                                                                                                                                                    |
| <code>ev_type char</code>                                         | Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE                                                                                                               |
| <code>ev_enabled char</code>                                      | Controls in which session_replication_role modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always. |
| <code>is_instead bool</code>                                      | True if the rule is an INSTEAD rule                                                                                                                                                           |
| <code>ev_qual pg_node_tree</code>                                 | Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition                                                                             |
| <code>ev_action pg_node_tree</code>                               | Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action                                                                                                |

### Note

`pg_class.relhasrules` must be true if a table has any rules in this catalog.

## 52.46. `pg_sec_label`

The catalog `pg_sec_label` stores security labels on database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 53.23.

See also `pg_shsec_label`, which performs a similar function for security labels of database objects that are shared across a database cluster.

**Table 52.46. `pg_sec_label` Columns**

| Column Type                | Description                                                                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>objoid oid</code>    | (references any OID column)<br>The OID of the object this security label pertains to                                                                                                              |
| <code>classoid oid</code>  | (references <code>pg_class.oid</code> )<br>The OID of the system catalog this object appears in                                                                                                   |
| <code>objsubid int4</code> | For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero. |
| <code>provider text</code> | The label provider associated with this label.                                                                                                                                                    |
| <code>label text</code>    | The security label applied to this object.                                                                                                                                                        |

## 52.47. `pg_sequence`

The catalog `pg_sequence` contains information about sequences. Some of the information about sequences, such as the name and the schema, is in `pg_class`

**Table 52.47. `pg_sequence` Columns**

| Column Type                    | Description                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------|
| <code>seqrelid oid</code>      | (references <code>pg_class.oid</code> )<br>The OID of the <code>pg_class</code> entry for this sequence |
| <code>seqtypeid oid</code>     | (references <code>pg_type.oid</code> )<br>Data type of the sequence                                     |
| <code>seqstart int8</code>     | Start value of the sequence                                                                             |
| <code>seqincrement int8</code> | Increment value of the sequence                                                                         |
| <code>seqmax int8</code>       | Maximum value of the sequence                                                                           |
| <code>seqmin int8</code>       | Minimum value of the sequence                                                                           |
| <code>seqcache int8</code>     | Cache size of the sequence                                                                              |
| <code>seqcycle bool</code>     | Whether the sequence cycles                                                                             |

## 52.48. `pg_shdepend`

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

**Table 52.48. `pg_shdepend` Columns**

| Column Type                                                         | Description                                                                                                                                                                 |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbid oid</code> (references <code>pg_database.oid</code> )    | The OID of the database the dependent object is in, or zero for a shared object                                                                                             |
| <code>classid oid</code> (references <code>pg_class.oid</code> )    | The OID of the system catalog the dependent object is in                                                                                                                    |
| <code>objid oid</code> (references any OID column)                  | The OID of the specific dependent object                                                                                                                                    |
| <code>objsubid int4</code>                                          | For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero. |
| <code>refclassid oid</code> (references <code>pg_class.oid</code> ) | The OID of the system catalog the referenced object is in (must be a shared catalog)                                                                                        |
| <code>refobjid oid</code> (references any OID column)               | The OID of the specific referenced object                                                                                                                                   |
| <code>deptype char</code>                                           | A code defining the specific semantics of this dependency relationship; see text                                                                                            |

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**SHARED\_DEPENDENCY\_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED\_DEPENDENCY\_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

**SHARED\_DEPENDENCY\_INITACL (i)**

The referenced object (which must be a role) is mentioned in a `pg_init_privs` entry for the dependent object.

**SHARED\_DEPENDENCY\_POLICY (r)**

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

**SHARED\_DEPENDENCY\_TABLESPACE (t)**

The referenced object (which must be a tablespace) is mentioned as the tablespace for a relation that doesn't have storage.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles and tablespaces as referenced objects.

As in the `pg_depend` catalog, most objects created during `initdb` are considered “pinned”. No entries are made in `pg_shdepend` that would have a pinned object as either referenced or dependent object.

## 52.49. `pg_shdescription`

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

**Table 52.49. `pg_shdescription` Columns**

| Column Type                                                       | Description                                                  |
|-------------------------------------------------------------------|--------------------------------------------------------------|
| <code>objoid oid</code> (references any OID column)               | The OID of the object this description pertains to           |
| <code>classoid oid</code> (references <code>pg_class.oid</code> ) | The OID of the system catalog this object appears in         |
| <code>description text</code>                                     | Arbitrary text that serves as the description of this object |

## 52.50. `pg_shseclabel`

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 53.23.

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

**Table 52.50. `pg_shseclabel` Columns**

| Column Type                                                       | Description                                           |
|-------------------------------------------------------------------|-------------------------------------------------------|
| <code>objoid oid</code> (references any OID column)               | The OID of the object this security label pertains to |
| <code>classoid oid</code> (references <code>pg_class.oid</code> ) | The OID of the system catalog this object appears in  |
| <code>provider text</code>                                        | The label provider associated with this label.        |
| <code>label text</code>                                           | The security label applied to this object.            |

## 52.51. `pg_statistic`

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children or partitions, a second entry with `stainherit = true`

is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot's columns. For more information see `src/include/catalog/pg_statistic.h`.

`pg_statistic` should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Table 52.51. `pg_statistic` Columns**

| Column Type                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>starelid oid</code> (references <code>pg_class.oid</code> )          | The table or index that the described column belongs to                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>staattnum int2</code> (references <code>pg_attribute.attnum</code> ) | The number of the described column                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>stainherit bool</code>                                               | If true, the stats include values from child tables, not just the values in the specified relation                                                                                                                                                                                                                                                                                                                                                                       |
| <code>stanullfrac float4</code>                                            | The fraction of the column's entries that are null                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>stawidth int4</code>                                                 | The average stored width, in bytes, of nonnull entries                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>stadistinct float4</code>                                            | The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by <code>stadistinct = -0.4</code> . A zero value means the number of distinct values is unknown. |
| <code>stakindN int2</code>                                                 | A code number indicating the kind of statistics stored in the <i>N</i> th “slot” of the <code>pg_statistic</code> row.                                                                                                                                                                                                                                                                                                                                                   |
| <code>staopN oid</code> (references <code>pg_operator.oid</code> )         | An operator used to derive the statistics stored in the <i>N</i> th “slot”. For example, a histogram slot would show the <code>&lt;</code> operator that defines the sort order of the data. Zero if the statistics kind does not require an operator.                                                                                                                                                                                                                   |
| <code>stacollN oid</code> (references <code>pg_collation.oid</code> )      | The collation used to derive the statistics stored in the <i>N</i> th “slot”. For example, a histogram slot for a collatable column would show the collation that defines the sort order of the data. Zero for noncollatable data.                                                                                                                                                                                                                                       |
| <code>stanumbersN float4[]</code>                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Column Type                      | Description                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  | Numerical statistics of the appropriate kind for the <i>N</i> th “slot”, or null if the slot kind does not involve numerical values                                                                                                                                                                                                                             |
| <code>stavaluesN anyarray</code> | Column data values of the appropriate kind for the <i>N</i> th “slot”, or null if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, or a related type such as an array's element type, so there is no way to define these columns' type more specifically than <code>anyarray</code> . |

## 52.52. `pg_statistic_ext`

The catalog `pg_statistic_ext` holds definitions of extended planner statistics. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

**Table 52.52. `pg_statistic_ext` Columns**

| Column Type                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <code>stxnamespace oid (references pg_namespace.oid)</code>      | The OID of the namespace that contains this statistics object                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>stxowner oid (references pg_authid.oid)</code>             | Owner of the statistics object                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>stxkeys int2vector (references pg_attribute.attnum)</code> | An array of attribute numbers, indicating which table columns are covered by this statistics object; for example a value of <code>1 3</code> would mean that the first and the third table columns are covered                                                                                                                                                                                                                                                 |
| <code>stxstattarget int2</code>                                  | <code>stxstattarget</code> controls the level of detail of statistics accumulated for this statistics object by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A null value says to use the maximum of the statistics targets of the referenced columns, if set, or the system default statistics target. Positive values of <code>stxstattarget</code> determine the target number of “most common values” to collect. |
| <code>stxkind char[]</code>                                      | An array containing codes for the enabled statistics kinds; valid values are: <code>d</code> for n-distinct statistics, <code>f</code> for functional dependency statistics, <code>m</code> for most common values (MCV) list statistics, and <code>e</code> for expression statistics                                                                                                                                                                         |
| <code>stxexprs pg_node_tree</code>                               | Expression trees (in <code>nodeToString()</code> representation) for statistics object attributes that are not simple column references. This is a list with one element per expression. Null if all statistics object attributes are simple references.                                                                                                                                                                                                       |

The `pg_statistic_ext` entry is filled in completely during `CREATE STATISTICS`, but the actual statistical values are not computed then. Subsequent `ANALYZE` commands compute the desired values and populate an entry in the `pg_statistic_ext_data` catalog.

## 52.53. `pg_statistic_ext_data`

The catalog `pg_statistic_ext_data` holds data for extended planner statistics defined in `pg_statistic_ext`. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

Normally there is one entry, with `stxdinherit = false`, for each statistics object that has been analyzed. If the table has inheritance children or partitions, a second entry with `stxdinherit = true` is also created. This row represents the statistics object over the inheritance tree, i.e., statistics for the data you'd see with `SELECT * FROM table*`, whereas the `stxdinherit = false` row represents the results of `SELECT * FROM ONLY table`.

Like `pg_statistic`, `pg_statistic_ext_data` should not be readable by the public, since the contents might be considered sensitive. (Example: most common combinations of values in columns might be quite interesting.) `pg_stats_ext` is a publicly readable view on `pg_statistic_ext_data` (after joining with `pg_statistic_ext`) that only exposes information about tables the current user owns.

**Table 52.53. `pg_statistic_ext_data` Columns**

| Column Type                                   | Description                                                                                                           |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>stxoid oid</code>                       | (references <code>pg_statistic_ext.oid</code> )<br>Extended statistics object containing the definition for this data |
| <code>stxdinherit bool</code>                 | If true, the stats include values from child tables, not just the values in the specified relation                    |
| <code>stxdndistinct pg_ndistinct</code>       | N-distinct counts, serialized as <code>pg_ndistinct</code> type                                                       |
| <code>stxddependencies pg_dependencies</code> | Functional dependency statistics, serialized as <code>pg_dependencies</code> type                                     |
| <code>stxdmcv pg_mcv_list</code>              | MCV (most-common values) list statistics, serialized as <code>pg_mcv_list</code> type                                 |
| <code>stxdexpr pg_statistic[]</code>          | Per-expression statistics, serialized as an array of <code>pg_statistic</code> type                                   |

## 52.54. `pg_subscription`

The catalog `pg_subscription` contains all existing logical replication subscriptions. For more information about logical replication see Chapter 29.

Unlike most system catalogs, `pg_subscription` is shared across all databases of a cluster: there is only one copy of `pg_subscription` per cluster, not one per database.

Access to the column `subconninfo` is revoked from normal users, because it could contain plain-text passwords.

**Table 52.54. `pg_subscription` Columns**

| Column Type                    | Description                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------|
| <code>oid oid</code>           | Row identifier                                                                                     |
| <code>subdbid oid</code>       | (references <code>pg_database.oid</code> )<br>OID of the database that the subscription resides in |
| <code>subskiplsn pg_lsn</code> |                                                                                                    |

| Column Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | Finish LSN of the transaction whose changes are to be skipped, if a valid LSN; otherwise 0/0.                                                                                                                                                                                                                                                                                                                                 |
| subname name                            | Name of the subscription                                                                                                                                                                                                                                                                                                                                                                                                      |
| subowner oid (references pg_authid.oid) | Owner of the subscription                                                                                                                                                                                                                                                                                                                                                                                                     |
| subenabled bool                         | If true, the subscription is enabled and should be replicating                                                                                                                                                                                                                                                                                                                                                                |
| subbinary bool                          | If true, the subscription will request that the publisher send data in binary format                                                                                                                                                                                                                                                                                                                                          |
| substream char                          | Controls how to handle the streaming of in-progress transactions: <b>f</b> = disallow streaming of in-progress transactions, <b>t</b> = spill the changes of in-progress transactions to disk and apply at once after the transaction is committed on the publisher and received by the subscriber, <b>p</b> = apply changes directly using a parallel apply worker if available (same as <b>t</b> if no worker is available) |
| subtwophasestate char                   | State codes for two-phase mode: <b>d</b> = disabled, <b>p</b> = pending enablement, <b>e</b> = enabled                                                                                                                                                                                                                                                                                                                        |
| subdisableonerr bool                    | If true, the subscription will be disabled if one of its workers detects an error                                                                                                                                                                                                                                                                                                                                             |
| subpasswordrequired bool                | If true, the subscription will be required to specify a password for authentication                                                                                                                                                                                                                                                                                                                                           |
| subrunasowner bool                      | If true, the subscription will be run with the permissions of the subscription owner                                                                                                                                                                                                                                                                                                                                          |
| subfailover bool                        | If true, the associated replication slots (i.e. the main slot and the table synchronization slots) in the upstream database are enabled to be synchronized to the standbys                                                                                                                                                                                                                                                    |
| subconninfo text                        | Connection string to the upstream database                                                                                                                                                                                                                                                                                                                                                                                    |
| subslotname name                        | Name of the replication slot in the upstream database (also used for the local replication origin name); null represents <b>NONE</b>                                                                                                                                                                                                                                                                                          |
| subsynccommit text                      | The synchronous_commit setting for the subscription's workers to use                                                                                                                                                                                                                                                                                                                                                          |
| subpublications text[]                  | Array of subscribed publication names. These reference publications defined in the upstream database. For more on publications see Section 29.1.                                                                                                                                                                                                                                                                              |
| suborigin text                          | The origin value must be either <b>none</b> or <b>any</b> . The default is <b>any</b> . If <b>none</b> , the subscription will request the publisher to only send changes that don't have an origin. If <b>any</b> , the publisher sends changes regardless of their origin.                                                                                                                                                  |

## 52.55. pg\_subscription\_rel

The catalog `pg_subscription_rel` contains the state for each replicated relation in each subscription. This is a many-to-many mapping.

This catalog only contains tables known to the subscription after running either `CREATE SUBSCRIPTION` or `ALTER SUBSCRIPTION ... REFRESH PUBLICATION`.

**Table 52.55. pg\_subscription\_rel Columns**

| Column Type                                  | Description                                                                                                                                                        |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srsubid oid (references pg_subscription.oid) | Reference to subscription                                                                                                                                          |
| srrelid oid (references pg_class.oid)        | Reference to relation                                                                                                                                              |
| srsubstate char                              | State code: <b>i</b> = initialize, <b>d</b> = data is being copied, <b>f</b> = finished table copy, <b>s</b> = synchronized, <b>r</b> = ready (normal replication) |
| srsublsn pg_lsn                              | Remote LSN of the state change used for synchronization coordination when in <b>s</b> or <b>r</b> states, otherwise null                                           |

## 52.56. pg\_tablespace

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

**Table 52.56. pg\_tablespace Columns**

| Column Type                             | Description                                              |
|-----------------------------------------|----------------------------------------------------------|
| oid oid                                 | Row identifier                                           |
| spcname name                            | Tablespace name                                          |
| spcowner oid (references pg_authid.oid) | Owner of the tablespace, usually the user who created it |
| spcacl aclitem[]                        | Access privileges; see Section 5.8 for details           |
| spcoptions text[]                       | Tablespace-level options, as “keyword=value” strings     |

## 52.57. pg\_transform

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See `CREATE TRANSFORM` for more information.

**Table 52.57. pg\_transform Columns**

| Column Type                              | Description                                |
|------------------------------------------|--------------------------------------------|
| oid oid                                  | Row identifier                             |
| trftype oid (references pg_type.oid)     | OID of the data type this transform is for |
| trflang oid (references pg_language.oid) | OID of the language this transform is for  |

| Column Type                                                            | Description                                                                                                                                                                           |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>trffromsql regproc</code> (references <code>pg_proc.oid</code> ) | The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if the default behavior should be used. |
| <code>trftosql regproc</code> (references <code>pg_proc.oid</code> )   | The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if the default behavior should be used.     |

## 52.58. `pg_trigger`

The catalog `pg_trigger` stores triggers on tables and views. See `CREATE TRIGGER` for more information.

**Table 52.58. `pg_trigger` Columns**

| Column Type                                                                | Description                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                       | Row identifier                                                                                                                                                                                                                                                                |
| <code>tgrelid oid</code> (references <code>pg_class.oid</code> )           | The table this trigger is on                                                                                                                                                                                                                                                  |
| <code>tgparentid oid</code> (references <code>pg_trigger.oid</code> )      | Parent trigger that this trigger is cloned from (this happens when partitions are created or attached to a partitioned table); zero if not a clone                                                                                                                            |
| <code>tgname name</code>                                                   | Trigger name (must be unique among triggers of same table)                                                                                                                                                                                                                    |
| <code>tgfoid oid</code> (references <code>pg_proc.oid</code> )             | The function to be called                                                                                                                                                                                                                                                     |
| <code>tgtype int2</code>                                                   | Bit mask identifying trigger firing conditions                                                                                                                                                                                                                                |
| <code>tgenabled char</code>                                                | Controls in which session <code>replication_role</code> modes the trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always. |
| <code>tgisinternal bool</code>                                             | True if trigger is internally generated (usually, to enforce the constraint identified by <code>tgconstraint</code> )                                                                                                                                                         |
| <code>tgconstrrelid oid</code> (references <code>pg_class.oid</code> )     | The table referenced by a referential integrity constraint (zero if trigger is not for a referential integrity constraint)                                                                                                                                                    |
| <code>tgconstrindid oid</code> (references <code>pg_class.oid</code> )     | The index supporting a unique, primary key, referential integrity, or exclusion constraint (zero if trigger is not for one of these types of constraint)                                                                                                                      |
| <code>tgconstraint oid</code> (references <code>pg_constraint.oid</code> ) | The <code>pg_constraint</code> entry associated with the trigger (zero if trigger is not for a constraint)                                                                                                                                                                    |
| <code>tgdeferrable bool</code>                                             | True if constraint trigger is deferrable                                                                                                                                                                                                                                      |
| <code>tginitdeferred bool</code>                                           |                                                                                                                                                                                                                                                                               |

| Column Type                                                                   | Description                                                                                                              |
|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
|                                                                               | True if constraint trigger is initially deferred                                                                         |
| <code>tgargs int2</code>                                                      | Number of argument strings passed to trigger function                                                                    |
| <code>tgattr int2vector</code> (references <code>pg_attribute.attnum</code> ) | Column numbers, if trigger is column-specific; otherwise an empty array                                                  |
| <code>tgargs bytea</code>                                                     | Argument strings to pass to trigger, each NULL-terminated                                                                |
| <code>tgqual pg_node_tree</code>                                              | Expression tree (in <code>nodeToString()</code> representation) for the trigger's <b>WHEN</b> condition, or null if none |
| <code>tgoldtable name</code>                                                  | <b>REFERENCING</b> clause name for <b>OLD</b> <b>TABLE</b> , or null if none                                             |
| <code>tgnewtable name</code>                                                  | <b>REFERENCING</b> clause name for <b>NEW</b> <b>TABLE</b> , or null if none                                             |

Currently, column-specific triggering is supported only for **UPDATE** events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

**Note**

When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

**Note**

`pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

# 52.59. pg\_ts\_config

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser's output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 52.59. pg\_ts\_config Columns**

| Column Type                                                               | Description                    |
|---------------------------------------------------------------------------|--------------------------------|
| <code>oid oid</code>                                                      | Row identifier                 |
| <code>cfgname name</code>                                                 | Text search configuration name |
| <code>cfgnamespace oid</code> (references <code>pg_namespace.oid</code> ) |                                |

| Column Type                                 | Description                                               |
|---------------------------------------------|-----------------------------------------------------------|
|                                             | The OID of the namespace that contains this configuration |
| cfgowner oid (references pg_authid.oid)     | Owner of the configuration                                |
| cfgparser oid (references pg_ts_parser.oid) | The OID of the text search parser for this configuration  |

## 52.60. pg\_ts\_config\_map

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration's parser.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 52.60. pg\_ts\_config\_map Columns**

| Column Type                              | Description                                                          |
|------------------------------------------|----------------------------------------------------------------------|
| mapcfg oid (references pg_ts_config.oid) | The OID of the <code>pg_ts_config</code> entry owning this map entry |
| maptokentype int4                        | A token type emitted by the configuration's parser                   |
| mapseqno int4                            | Order in which to consult this entry (lower mapseqnos first)         |
| mapdict oid (references pg_ts_dict.oid)  | The OID of the text search dictionary to consult                     |

## 52.61. pg\_ts\_dict

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 52.61. pg\_ts\_dict Columns**

| Column Type                                      | Description                                             |
|--------------------------------------------------|---------------------------------------------------------|
| oid oid                                          | Row identifier                                          |
| dictname name                                    | Text search dictionary name                             |
| dictnamespace oid (references pg_namespace.oid)  | The OID of the namespace that contains this dictionary  |
| dictowner oid (references pg_authid.oid)         | Owner of the dictionary                                 |
| dicttemplate oid (references pg_ts_template.oid) | The OID of the text search template for this dictionary |
| dictinitoption text                              |                                                         |

| Column Type                                   |
|-----------------------------------------------|
| Description                                   |
| Initialization option string for the template |

## 52.62. pg\_ts\_parser

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 52.62. pg\_ts\_parser Columns**

| Column Type                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------|
| Description                                                                                                                    |
| <code>oid oid</code><br>Row identifier                                                                                         |
| <code>prsname name</code><br>Text search parser name                                                                           |
| <code>pramespace oid</code> (references <code>pg_namespace.oid</code> )<br>The OID of the namespace that contains this parser  |
| <code>prsstart regproc</code> (references <code>pg_proc.oid</code> )<br>OID of the parser's startup function                   |
| <code>prstoken regproc</code> (references <code>pg_proc.oid</code> )<br>OID of the parser's next-token function                |
| <code>prsend regproc</code> (references <code>pg_proc.oid</code> )<br>OID of the parser's shutdown function                    |
| <code>prshadline regproc</code> (references <code>pg_proc.oid</code> )<br>OID of the parser's headline function (zero if none) |
| <code>prsllextype regproc</code> (references <code>pg_proc.oid</code> )<br>OID of the parser's lextype function                |

## 52.63. pg\_ts\_template

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 52.63. pg\_ts\_template Columns**

| Column Type                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------|
| Description                                                                                                                          |
| <code>oid oid</code><br>Row identifier                                                                                               |
| <code>tmplname name</code><br>Text search template name                                                                              |
| <code>tmplnamespace oid</code> (references <code>pg_namespace.oid</code> )<br>The OID of the namespace that contains this template   |
| <code>tmplinit regproc</code> (references <code>pg_proc.oid</code> )<br>OID of the template's initialization function (zero if none) |

| Column Type                                                            | Description                           |
|------------------------------------------------------------------------|---------------------------------------|
| <code>tmpllexize regproc</code> (references <code>pg_proc.oid</code> ) | OID of the template's lexize function |

## 52.64. `pg_type`

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 52.64. `pg_type` Columns**

| Column Type                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oid oid</code>                                                      | Row identifier                                                                                                                                                                                                                                                                                                                                                                                |
| <code>typname name</code>                                                 | Data type name                                                                                                                                                                                                                                                                                                                                                                                |
| <code>typnamespace oid</code> (references <code>pg_namespace.oid</code> ) | The OID of the namespace that contains this type                                                                                                                                                                                                                                                                                                                                              |
| <code>typowner oid</code> (references <code>pg_authid.oid</code> )        | Owner of the type                                                                                                                                                                                                                                                                                                                                                                             |
| <code>typlen int2</code>                                                  | For a fixed-size type, <code>typlen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typlen</code> is negative. -1 indicates a “varlena” type (one that has a length word), -2 indicates a null-terminated C string.                                                                                                           |
| <code>typbyval bool</code>                                                | <code>typbyval</code> determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typlen</code> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value. |
| <code>typtype char</code>                                                 | <code>typtype</code> is <code>b</code> for a base type, <code>c</code> for a composite type (e.g., a table's row type), <code>d</code> for a domain, <code>e</code> for an enum type, <code>p</code> for a pseudo-type, <code>r</code> for a range type, or <code>m</code> for a multi-range type. See also <code>typrelid</code> and <code>typbasetype</code> .                              |
| <code>typcategory char</code>                                             | <code>typcategory</code> is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 52.65.                                                                                                                                                                                                                    |
| <code>typispreferred bool</code>                                          | True if the type is a preferred cast target within its <code>typcategory</code>                                                                                                                                                                                                                                                                                                               |
| <code>typisdefined bool</code>                                            | True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <code>typisdefined</code> is false, nothing except the type name, namespace, and OID can be relied on.                                                                                                                                                                                     |
| <code>typdelim char</code>                                                | Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.                                                                                                                                                                                                                   |
| <code>typrelid oid</code> (references <code>pg_class.oid</code> )         | If this is a composite type (see <code>typtype</code> ), then this column points to the <code>pg_class</code> entry that defines the corresponding table. (For a free-standing composite type, the                                                                                                                                                                                            |

| Column Type<br>Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pg_class</code> entry doesn't really represent a table, but it is needed anyway for the type's <code>pg_attribute</code> entries to link to.) Zero for non-composite types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>typsubscript</code> regproc (references <code>pg_proc.oid</code> )<br>Subscripting handler function's OID, or zero if this type doesn't support subscripting. Types that are “true” array types have <code>typsubscript = array_subscript_handler</code> , but other types may have other handler functions to implement specialized subscripting behavior.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>typelem</code> oid (references <code>pg_type.oid</code> )<br>If <code>typelem</code> is not zero then it identifies another row in <code>pg_type</code> , defining the type yielded by subscripting. This should be zero if <code>typsubscript</code> is zero. However, it can be zero when <code>typsubscript</code> isn't zero, if the handler doesn't need <code>typelem</code> to determine the subscripting result type. Note that a <code>typelem</code> dependency is considered to imply physical containment of the element type in this type; so DDL changes on the element type might be restricted by the presence of this type.                                                                                                                                                                                                                                                                                    |
| <code>typarray</code> oid (references <code>pg_type.oid</code> )<br>If <code>typarray</code> is not zero then it identifies another row in <code>pg_type</code> , which is the “true” array type having this type as element                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <code>typalign</code> char<br><code>typalign</code> is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are: <ul style="list-style-type: none"> <li>• <code>c</code> = <code>char</code> alignment, i.e., no alignment needed.</li> <li>• <code>s</code> = <code>short</code> alignment (2 bytes on most machines).</li> <li>• <code>i</code> = <code>int</code> alignment (4 bytes on most machines).</li> <li>• <code>d</code> = <code>double</code> alignment (8 bytes on many machines, but by no means all).</li> </ul> |
| <code>typstorage</code> char<br><code>typstorage</code> tells for varlena types (those with <code>typ len = -1</code> ) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Note that <b>m</b> values can also be moved out to secondary storage, but only as a last resort (<b>e</b> and <b>x</b> values are moved first).</p> |
| <code>typnotnull bool</code>                                              | <code>typnotnull</code> represents a not-null constraint on a type. Used for domains only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>typbasetype oid</code> (references <code>pg_type.oid</code> )       | If this is a domain (see <code>typtype</code> ), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>tytypmod int4</code>                                                | Domains use <code>tytypmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code> ). -1 if this type is not a domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>typndims int4</code>                                                | <code>typndims</code> is the number of array dimensions for a domain over an array (that is, <code>typbasetype</code> is an array type). Zero for types other than domains over array types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>typcollation oid</code> (references <code>pg_collation.oid</code> ) | <code>typcollation</code> specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have a nonzero value here, typically <code>DEFAULT_COLLATION_OID</code> . A domain over a collatable type can have a collation OID different from its base type's, if one was specified for the domain.                                                                                                                                                                                                                                                                                                              |
| <code>typdefaultbin pg_node_tree</code>                                   | If <code>typdefaultbin</code> is not null, it is the <code>nodeToString()</code> representation of a default expression for the type. This is only used for domains.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>typdefault text</code>                                              | <code>typdefault</code> is null if the type has no associated default value. If <code>typdefaultbin</code> is not null, <code>typdefault</code> must contain a human-readable version of the default expression represented by <code>typdefaultbin</code> . If <code>typdefaultbin</code> is null and <code>typdefault</code> is not, then <code>typdefault</code> is the external representation of the type's default value, which can be fed to the type's input converter to produce a constant.                                                                                                                                                                                      |
| <code>typaclaclitem[]</code>                                              | Access privileges; see Section 5.8 for details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Note

For fixed-width types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.

Table 52.65 lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

Table 52.65. `typcategory` Codes

| Code | Category              |
|------|-----------------------|
| A    | Array types           |
| B    | Boolean types         |
| C    | Composite types       |
| D    | Date/time types       |
| E    | Enum types            |
| G    | Geometric types       |
| I    | Network address types |
| N    | Numeric types         |
| P    | Pseudo-types          |
| R    | Range types           |
| S    | String types          |
| T    | Timespan types        |
| U    | User-defined types    |
| V    | Bit-string types      |
| X    | unknown type          |
| Z    | Internal-use types    |

## 52.65. `pg_user_mapping`

The catalog `pg_user_mapping` stores the mappings from local user to remote. Access to this catalog is restricted from normal users, use the view `pg_user_mappings` instead.

Table 52.66. `pg_user_mapping` Columns

| Column Type                                                                | Description                                                               |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <code>oid oid</code>                                                       | Row identifier                                                            |
| <code>umuser oid</code> (references <code>pg_authid.oid</code> )           | OID of the local role being mapped, or zero if the user mapping is public |
| <code>umserver oid</code> (references <code>pg_foreign_server.oid</code> ) | The OID of the foreign server that contains this mapping                  |
| <code>umoptions text[]</code>                                              | User mapping specific options, as “keyword=value” strings                 |

---

# Chapter 53. System Views

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 35) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it's usually better to use the information schema if it provides all the information you need.

Table 53.1 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to accumulated statistics; they are described in Table 27.2.

## 53.1. Overview

Table 53.1 lists the system views. More detailed documentation of each catalog follows below. Except where noted, all the views described here are read-only.

**Table 53.1. System Views**

| View Name                       | Purpose                                                               |
|---------------------------------|-----------------------------------------------------------------------|
| pg_aios                         | In-use asynchronous IO handles                                        |
| pg_available_extensions         | available extensions                                                  |
| pg_available_extension_versions | available versions of extensions                                      |
| pg_backend_memory_contexts      | backend memory contexts                                               |
| pg_config                       | compile-time configuration parameters                                 |
| pg_cursors                      | open cursors                                                          |
| pg_file_settings                | summary of configuration file contents                                |
| pg_group                        | groups of database users                                              |
| pg_hba_file_rules               | summary of client authentication configuration file contents          |
| pg_ident_file_mappings          | summary of client user name mapping configuration file contents       |
| pg_indexes                      | indexes                                                               |
| pg_locks                        | locks currently held or awaited                                       |
| pg_matviews                     | materialized views                                                    |
| pg_policies                     | policies                                                              |
| pg_prepared_statements          | prepared statements                                                   |
| pg_prepared_xacts               | prepared transactions                                                 |
| pg_publication_tables           | publications and information of their associated tables               |
| pg_replication_origin_status    | information about replication origins, including replication progress |
| pg_replication_slots            | replication slot information                                          |
| pg_roles                        | database roles                                                        |
| pg_rules                        | rules                                                                 |
| pg_seclabels                    | security labels                                                       |

| View Name                 | Purpose                                          |
|---------------------------|--------------------------------------------------|
| pg_sequences              | sequences                                        |
| pg_settings               | parameter settings                               |
| pg_shadow                 | database users                                   |
| pg_shmem_allocations      | shared memory allocations                        |
| pg_shmem_allocations_numa | NUMA node mappings for shared memory allocations |
| pg_stats                  | planner statistics                               |
| pg_stats_ext              | extended planner statistics                      |
| pg_stats_ext_exprs        | extended planner statistics for expressions      |
| pg_tables                 | tables                                           |
| pg_timezone_abbrevs       | time zone abbreviations                          |
| pg_timezone_names         | time zone names                                  |
| pg_user                   | database users                                   |
| pg_user_mappings          | user mappings                                    |
| pg_views                  | views                                            |
| pg_wait_events            | wait events                                      |

## 53.2. pg\_aios

The `pg_aios` view lists all Asynchronous I/O handles that are currently in-use. An I/O handle is used to reference an I/O operation that is being prepared, executed or is in the process of completing. `pg_aios` contains one row for each I/O handle.

This view is mainly useful for developers of PostgreSQL, but may also be useful when tuning PostgreSQL.

**Table 53.2. `pg_aios` Columns**

| Column Type<br>Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pid int4</code><br>Process ID of the server process that is issuing this I/O.                                                                                                                                                                                                                                                                                                                                                                     |
| <code>io_id int4</code><br>Identifier of the I/O handle. Handles are reused once the I/O completed (or if the handle is released before I/O is started). On reuse <code>pg_aios.io_generation</code> is incremented.                                                                                                                                                                                                                                    |
| <code>io_generation int8</code><br>Generation of the I/O handle.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>state text</code><br>State of the I/O handle: <ul style="list-style-type: none"> <li>• <code>HANDED_OUT</code>, referenced by code but not yet used</li> <li>• <code>DEFINED</code>, information necessary for execution is known</li> <li>• <code>STAGED</code>, ready for execution</li> <li>• <code>SUBMITTED</code>, submitted for execution</li> <li>• <code>COMPLETED_IO</code>, finished, but result has not yet been processed</li> </ul> |

| Column                 | Type        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                        |             | <ul style="list-style-type: none"> <li>• <b>COMPLETED_SHARED</b>, shared completion processing completed</li> <li>• <b>COMPLETED_LOCAL</b>, backend local completion processing completed</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>operation</b>       | <b>text</b> | Operation performed using the I/O handle: <ul style="list-style-type: none"> <li>• <b>invalid</b>, not yet known</li> <li>• <b>readv</b>, a vectored read</li> <li>• <b>writew</b>, a vectored write</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>off</b>             | <b>int8</b> | Offset of the I/O operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>length</b>          | <b>int8</b> | Length of the I/O operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>target</b>          | <b>text</b> | What kind of object is the I/O targeting: <ul style="list-style-type: none"> <li>• <b>smgr</b>, I/O on relations</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>handle_data_len</b> | <b>int2</b> | Length of the data associated with the I/O operation. For I/O to/from <b>shared_buffers</b> and <b>temp_buffers</b> , this indicates the number of buffers the I/O is operating on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>raw_result</b>      | <b>int4</b> | Low-level result of the I/O operation, or NULL if the operation has not yet completed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>result</b>          | <b>text</b> | High-level result of the I/O operation: <ul style="list-style-type: none"> <li>• <b>UNKNOWN</b> means that the result of the operation is not yet known.</li> <li>• <b>OK</b> means the I/O completed successfully.</li> <li>• <b>PARTIAL</b> means that the I/O completed without error, but did not process all data. Commonly callers will need to retry and perform the remainder of the work in a separate I/O.</li> <li>• <b>WARNING</b> means that the I/O completed without error, but that execution of the IO triggered a warning. E.g. when encountering a corrupted buffer with <b>zero_damaged_pages</b> enabled.</li> <li>• <b>ERROR</b> means the I/O failed with an error.</li> </ul> |
| <b>target_desc</b>     | <b>text</b> | Description of what the I/O operation is targeting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>f_sync</b>          | <b>bool</b> | Flag indicating whether the I/O is executed synchronously.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>f_localmem</b>      | <b>bool</b> | Flag indicating whether the I/O references process local memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>f_buffered</b>      | <b>bool</b> | Flag indicating whether the I/O is buffered I/O.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

The **pg\_aios** view is read-only.

By default, the **pg\_aios** view can be read only by superusers or roles with privileges of the **pg\_read\_all\_stats** role.

## 53.3. pg\_available\_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 53.3. pg\_available\_extensions Columns**

| Column Type            | Description                                                            |
|------------------------|------------------------------------------------------------------------|
| name name              | Extension name                                                         |
| default_version text   | Name of default version, or NULL if none is specified                  |
| installed_version text | Currently installed version of the extension, or NULL if not installed |
| comment text           | Comment string from the extension's control file                       |

The `pg_available_extensions` view is read-only.

## 53.4. pg\_available\_extension\_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 53.4. pg\_available\_extension\_versions Columns**

| Column Type      | Description                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------|
| name name        | Extension name                                                                                          |
| version text     | Version name                                                                                            |
| installed bool   | True if this version of this extension is currently installed                                           |
| superuser bool   | True if only superusers are allowed to install this extension (but see <code>trusted</code> )           |
| trusted bool     | True if the extension can be installed by non-superusers with appropriate privileges                    |
| relocatable bool | True if extension can be relocated to another schema                                                    |
| schema name      | Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable |
| requires name[]  | Names of prerequisite extensions, or NULL if none                                                       |
| comment text     | Comment string from the extension's control file                                                        |

The `pg_available_extension_versions` view is read-only.

## 53.5. pg\_backend\_memory\_contexts

The view `pg_backend_memory_contexts` displays all the memory contexts of the server process attached to the current session.

`pg_backend_memory_contexts` contains one row for each memory context.

**Table 53.5. pg\_backend\_memory\_contexts Columns**

| Column                     | Type                | Description                                                                                                                                                                                                                                                         |
|----------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>          | <code>text</code>   | Name of the memory context                                                                                                                                                                                                                                          |
| <code>ident</code>         | <code>text</code>   | Identification information of the memory context. This field is truncated at 1024 bytes                                                                                                                                                                             |
| <code>type</code>          | <code>text</code>   | Type of the memory context                                                                                                                                                                                                                                          |
| <code>level</code>         | <code>int4</code>   | The 1-based level of the context in the memory context hierarchy. The level of a context also shows the position of that context in the <code>path</code> column.                                                                                                   |
| <code>path</code>          | <code>int4[]</code> | Array of transient numerical identifiers to describe the memory context hierarchy. The first element is for <code>TopMemoryContext</code> , subsequent elements contain intermediate parents and the final element contains the identifier for the current context. |
| <code>total_bytes</code>   | <code>int8</code>   | Total bytes allocated for this memory context                                                                                                                                                                                                                       |
| <code>total_nblocks</code> | <code>int8</code>   | Total number of blocks allocated for this memory context                                                                                                                                                                                                            |
| <code>free_bytes</code>    | <code>int8</code>   | Free space in bytes                                                                                                                                                                                                                                                 |
| <code>free_chunks</code>   | <code>int8</code>   | Total number of free chunks                                                                                                                                                                                                                                         |
| <code>used_bytes</code>    | <code>int8</code>   | Used space in bytes                                                                                                                                                                                                                                                 |

By default, the `pg_backend_memory_contexts` view can be read only by superusers or roles with the privileges of the `pg_read_all_stats` role.

Since memory contexts are created and destroyed during the running of a query, the identifiers stored in the `path` column can be unstable between multiple invocations of the view in the same query. The example below demonstrates an effective usage of this column and calculates the total number of bytes used by `CacheMemoryContext` and all of its children:

```
WITH memory_contexts AS (
    SELECT * FROM pg_backend_memory_contexts
)
SELECT sum(c1.total_bytes)
FROM memory_contexts c1, memory_contexts c2
WHERE c2.name = 'CacheMemoryContext'
AND c1.path[c2.level] = c2.path[c2.level];
```

The Common Table Expression is used to ensure the context IDs in the `path` column match between both evaluations of the view.

## 53.6. pg\_config

The view `pg_config` describes the compile-time configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries. It provides the same basic information as the `pg_config` PostgreSQL client application.

By default, the `pg_config` view can be read only by superusers.

**Table 53.6. pg\_config Columns**

| Column Type  | Description         |
|--------------|---------------------|
| name text    | The parameter name  |
| setting text | The parameter value |

## 53.7. pg\_cursors

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the `DECLARE` statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 54.2.3
- via the Server Programming Interface (SPI), as described in Section 45.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

### Note

Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

**Table 53.7. pg\_cursors Columns**

| Column Type        | Description                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name text          | The name of the cursor                                                                                                                                               |
| statement text     | The verbatim query string submitted to declare this cursor                                                                                                           |
| is_holdable bool   | <code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise |
| is_binary bool     | <code>true</code> if the cursor was declared <code>BINARY</code> ; <code>false</code> otherwise                                                                      |
| is_scrollable bool |                                                                                                                                                                      |

| Column Type                                        | Description                                                                                                                   |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>true</code>                                  | if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); <code>false</code> otherwise |
| <code>creation_time</code> <code>timestampz</code> | The time at which the cursor was declared                                                                                     |

The `pg_cursors` view is read-only.

## 53.8. `pg_file_settings`

The view `pg_file_settings` provides a summary of the contents of the server's configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)

By default, the `pg_file_settings` view can be read only by superusers.

**Table 53.8. `pg_file_settings` Columns**

| Column Type                               | Description                                                                  |
|-------------------------------------------|------------------------------------------------------------------------------|
| <code>sourcefile</code> <code>text</code> | Full path name of the configuration file                                     |
| <code>sourceline</code> <code>int4</code> | Line number within the configuration file where the entry appears            |
| <code>seqno</code> <code>int4</code>      | Order in which the entries are processed (1.. <i>n</i> )                     |
| <code>name</code> <code>text</code>       | Configuration parameter name                                                 |
| <code>setting</code> <code>text</code>    | Value to be assigned to the parameter                                        |
| <code>applied</code> <code>bool</code>    | True if the value can be applied successfully                                |
| <code>error</code> <code>text</code>      | If not null, an error message indicating why this entry could not be applied |

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied` = false is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See Section 19.1 for more information about the various ways to change run-time parameters.

## 53.9. `pg_group`

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rol-canlogin`, which is an approximation to the set of roles that are being used as groups.

**Table 53.9. `pg_group` Columns**

| Column Type                                                            | Description                                            |
|------------------------------------------------------------------------|--------------------------------------------------------|
| <code>groname name</code> (references <code>pg_authid.rolname</code> ) | Name of the group                                      |
| <code>grosysid oid</code> (references <code>pg_authid.oid</code> )     | ID of this group                                       |
| <code>grolist oid[]</code> (references <code>pg_authid.oid</code> )    | An array containing the IDs of the roles in this group |

## 53.10. `pg_hba_file_rules`

The view `pg_hba_file_rules` provides a summary of the contents of the client authentication configuration file, `pg_hba.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the rule could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_hba_file_rules` view can be read only by superusers.

**Table 53.10. `pg_hba_file_rules` Columns**

| Column Type                   | Description                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rule_number int4</code> | Number of this rule, if valid, otherwise NULL. This indicates the order in which each rule is considered until a match is found during authentication. |
| <code>file_name text</code>   | Name of the file containing this rule                                                                                                                  |
| <code>line_number int4</code> | Line number of this rule in <code>file_name</code>                                                                                                     |
| <code>type text</code>        | Type of connection                                                                                                                                     |
| <code>database text[]</code>  | List of database name(s) to which this rule applies                                                                                                    |
| <code>user_name text[]</code> | List of user and group name(s) to which this rule applies                                                                                              |
| <code>address text</code>     | Host name or IP address, or one of <code>all</code> , <code>samehost</code> , or <code>samenet</code> , or null for local connections                  |
| <code>netmask text</code>     | IP address mask, or null if not applicable                                                                                                             |
| <code>auth_method text</code> | Authentication method                                                                                                                                  |
| <code>options text[]</code>   | Options specified for authentication method, if any                                                                                                    |

| Column Type<br>Description                                                                  |
|---------------------------------------------------------------------------------------------|
| error text<br>If not null, an error message indicating why this line could not be processed |

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See Chapter 20 for more information about client authentication configuration.

## 53.11. pg\_ident\_file\_mappings

The view `pg_ident_file_mappings` provides a summary of the contents of the client user name mapping configuration file, `pg_ident.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the map could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_ident_file_mappings` view can be read only by superusers.

**Table 53.11. pg\_ident\_file\_mappings Columns**

| Column Type<br>Description                                                                  |
|---------------------------------------------------------------------------------------------|
| map_number int4<br>Number of this map, in priority order, if valid, otherwise NULL          |
| file_name text<br>Name of the file containing this map                                      |
| line_number int4<br>Line number of this map in <code>file_name</code>                       |
| map_name text<br>Name of the map                                                            |
| sys_name text<br>Detected user name of the client                                           |
| pg_username text<br>Requested PostgreSQL user name                                          |
| error text<br>If not NULL, an error message indicating why this line could not be processed |

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See Chapter 20 for more information about client authentication configuration.

## 53.12. pg\_indexes

The view `pg_indexes` provides access to useful information about each index in the database.

**Table 53.12. pg\_indexes Columns**

| Column Type<br>Description                                      |
|-----------------------------------------------------------------|
| schemaname name (references <code>pg_namespace.nspname</code> ) |

| Column Type                                                             | Description                                                        |
|-------------------------------------------------------------------------|--------------------------------------------------------------------|
|                                                                         | Name of schema containing table and index                          |
| <b>tablename</b> name (references <code>pg_class.relname</code> )       | Name of table the index is for                                     |
| <b>indexname</b> name (references <code>pg_class.relname</code> )       | Name of index                                                      |
| <b>tablespace</b> name (references <code>pg_tablespace.spcname</code> ) | Name of tablespace containing index (null if default for database) |
| <b>indexdef</b> text                                                    | Index definition (a reconstructed CREATE INDEX command)            |

## 53.13. pg\_locks

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object, as is the right to update `pg_database.datfrozenxid`. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

**Table 53.13. pg\_locks Columns**

| Column Type                                                    | Description                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>locktype</b> text                                           | Type of the lockable object: <code>relation</code> , <code>extend</code> , <code>frozenid</code> , <code>page</code> , <code>tuple</code> , <code>transactionid</code> , <code>virtualxid</code> , <code>spectoken</code> , <code>object</code> , <code>userlock</code> , <code>advisory</code> , or <code>applytransaction</code> . (See also Table 27.11.) |
| <b>database oid</b> (references <code>pg_database.oid</code> ) | OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID                                                                                                                                                                                                                     |
| <b>relation oid</b> (references <code>pg_class.oid</code> )    | OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation                                                                                                                                                                                                                                                      |
| <b>page</b> int4                                               | Page number targeted by the lock within the relation, or null if the target is not a relation page or tuple                                                                                                                                                                                                                                                  |
| <b>tuple</b> int2                                              | Tuple number targeted by the lock within the page, or null if the target is not a tuple                                                                                                                                                                                                                                                                      |
| <b>virtualxid</b> text                                         | Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID; see Chapter 67                                                                                                                                                                                                                                    |
| <b>transactionid</b> xid                                       | ID of the transaction targeted by the lock, or null if the target is not a transaction ID; Chapter 67                                                                                                                                                                                                                                                        |

| Column                    | Type                            | Description                                                                                                                                                                                                             |
|---------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>classid</b>            | oid (references pg_class.oid)   | OID of the system catalog containing the lock target, or null if the target is not a general database object                                                                                                            |
| <b>objid</b>              | oid (references any OID column) | OID of the lock target within its system catalog, or null if the target is not a general database object                                                                                                                |
| <b>objsubid</b>           | int2                            | Column number targeted by the lock (the <b>classid</b> and <b>objid</b> refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object |
| <b>virtualtransaction</b> | text                            | Virtual ID of the transaction that is holding or awaiting this lock                                                                                                                                                     |
| <b>pid</b>                | int4                            | Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction                                                                                                   |
| <b>mode</b>               | text                            | Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)                                                                                                                           |
| <b>granted</b>            | bool                            | True if lock is held, false if lock is awaited                                                                                                                                                                          |
| <b>fastpath</b>           | bool                            | True if lock was taken via fast path, false if taken via main lock table                                                                                                                                                |
| <b>waitstart</b>          | timestampz                      | Time when the server process started waiting for this lock, or null if the lock is held. Note that this can be null for a very short period of time after the wait started even though <b>granted</b> is <b>false</b> . |

**granted** is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction's virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction's permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction's ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

A speculative insertion lock consists of a transaction ID and a speculative insertion token. The speculative insertion token is displayed in the **objid** column.

Advisory locks can be acquired on keys consisting of either a single **bigint** value or two integer values. A **bigint** key is displayed with its high-order half in the **classid** column, its low-order half in the **objid** column, and **objsubid** equal to 1. The original **bigint** value can be reassembled with the expression `(classid::bigint << 32) | objid::bigint`. Integer keys are displayed with the first key in the **classid** column, the second key in the **objid** column, and

`objsubid` equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the `database` column is meaningful for an advisory lock.

Apply transaction locks are used in parallel mode to apply the transaction in logical replication. The remote transaction ID is displayed in the `transactionid` column. The `objsubid` displays the lock subtype which is 0 for the lock used to synchronize the set of changes, and 1 for the lock used to wait for the transaction to finish to ensure commit order.

`pg_locks` provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its `relation` column can be joined against `pg_class.oid` to identify locked relations, this will only work correctly for relations in the current database (those for which the `database` column is either the current database's OID or zero).

The `pid` column can be joined to the `pid` column of the `pg_stat_activity` view to get more information on the session holding or awaiting each lock, for example

```
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
    ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the `virtualtransaction` column can be joined to the `transaction` column of the `pg_prepared_xacts` view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
    ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

While it is possible to obtain information about which processes block which other processes by joining `pg_locks` against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the `pg_locks` view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to use the `pg_blocking_pids()` function (see Table 9.71) to identify which process(es) a waiting process is blocked behind.

The `pg_locks` view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and *fast-path* locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with `fastpath = true`) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

## 53.14. `pg_matviews`

The view `pg_matviews` provides access to useful information about each materialized view in the database.

**Table 53.14. pg\_matviews Columns**

| Column Type                                        | Description                                                                    |
|----------------------------------------------------|--------------------------------------------------------------------------------|
| schemaname name (references pg_namespace.nspname)  | Name of schema containing materialized view                                    |
| matviewname name (references pg_class.relname)     | Name of materialized view                                                      |
| matviewowner name (references pg_authid.rolname)   | Name of materialized view's owner                                              |
| tablespace name (references pg_tablespace.spcname) | Name of tablespace containing materialized view (null if default for database) |
| hasindexes bool                                    | True if materialized view has (or recently had) any indexes                    |
| ispopulated bool                                   | True if materialized view is currently populated                               |
| definition text                                    | Materialized view definition (a reconstructed SELECT query)                    |

## 53.15. pg\_policies

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

**Table 53.15. pg\_policies Columns**

| Column Type                                       | Description                                                                                              |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| schemaname name (references pg_namespace.nspname) | Name of schema containing table policy is on                                                             |
| tablename name (references pg_class.relname)      | Name of table policy is on                                                                               |
| policyname name (references pg_policy.polname)    | Name of policy                                                                                           |
| permissive text                                   | Is the policy permissive or restrictive?                                                                 |
| roles name[]                                      | The roles to which this policy applies                                                                   |
| cmd text                                          | The command type to which the policy is applied                                                          |
| qual text                                         | The expression added to the security barrier qualifications for queries that this policy applies to      |
| with_check text                                   | The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table |

## 53.16. pg\_prepared\_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See `PREPARE` for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the `DEALLOCATE` command).

**Table 53.16. `pg_prepared_statements` Columns**

| Column Type                            | Description                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name text</code>                 | The identifier of the prepared statement                                                                                                                                                                                                                                                                                                                   |
| <code>statement text</code>            | The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.                                             |
| <code>prepare_time timestamptz</code>  | The time at which the prepared statement was created                                                                                                                                                                                                                                                                                                       |
| <code>parameter_types regtype[]</code> | The expected parameter types for the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> .                                                                                                                |
| <code>result_types regtype[]</code>    | The types of the columns returned by the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> . If the prepared statement does not provide a result (e.g., a DML statement), then this field will be null. |
| <code>from_sql bool</code>             | <code>true</code> if the prepared statement was created via the <code>PREPARE SQL</code> command; <code>false</code> if the statement was prepared via the frontend/backend protocol                                                                                                                                                                       |
| <code>generic_plans int8</code>        | Number of times generic plan was chosen                                                                                                                                                                                                                                                                                                                    |
| <code>custom_plans int8</code>         | Number of times custom plan was chosen                                                                                                                                                                                                                                                                                                                     |

The `pg_prepared_statements` view is read-only.

## 53.17. `pg_prepared_xacts`

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see `PREPARE TRANSACTION` for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

**Table 53.17. `pg_prepared_xacts` Columns**

| Column Type                       | Description                                                        |
|-----------------------------------|--------------------------------------------------------------------|
| <code>transaction xid</code>      | Numeric transaction identifier of the prepared transaction         |
| <code>gid text</code>             | Global transaction identifier that was assigned to the transaction |
| <code>prepared timestamptz</code> | Time at which the transaction was prepared for commit              |

| Column Type                                    | Description                                                |
|------------------------------------------------|------------------------------------------------------------|
| owner name (references pg_authid.rolname)      | Name of the user that executed the transaction             |
| database name (references pg_database.datname) | Name of the database in which the transaction was executed |

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

## 53.18. pg\_publication\_tables

The view `pg_publication_tables` provides information about the mapping between publications and information of tables they contain. Unlike the underlying catalog `pg_publication_rel`, this view expands publications defined as `FOR ALL TABLES` and `FOR TABLES IN SCHEMA`, so for such publications there will be a row for each eligible table.

**Table 53.18. pg\_publication\_tables Columns**

| Column Type                                       | Description                                                                                                                                                |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pubname name (references pg_publication.pubname)  | Name of publication                                                                                                                                        |
| schemaname name (references pg_namespace.nspname) | Name of schema containing table                                                                                                                            |
| tablename name (references pg_class.relname)      | Name of table                                                                                                                                              |
| attnames name[] (references pg_attribute.attname) | Names of table columns included in the publication. This contains all the columns of the table when the user didn't specify the column list for the table. |
| rowfilter text                                    | Expression for the table's publication qualifying condition                                                                                                |

## 53.19. pg\_replication\_origin\_status

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see Chapter 48.

**Table 53.19. pg\_replication\_origin\_status Columns**

| Column Type                                                | Description                                                                                                                                                        |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local_id oid (references pg_replication_origin.roident)    | internal node identifier                                                                                                                                           |
| external_id text (references pg_replication_origin.roname) | external node identifier                                                                                                                                           |
| remote_lsn pg_lsn                                          | The origin node's LSN up to which data has been replicated.                                                                                                        |
| local_lsn pg_lsn                                           | This node's LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits. |

## 53.20. pg\_replication\_slots

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see Section 26.2.6 and Chapter 47.

**Table 53.20. `pg_replication_slots` Columns**

| Column                           | Type                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>slot_name</code>           | <code>name</code>                                                | A unique, cluster-wide identifier for the replication slot                                                                                                                                                                                                                                                                                                                                         |
| <code>plugin</code>              | <code>name</code>                                                | The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.                                                                                                                                                                                                                                                                            |
| <code>slot_type</code>           | <code>text</code>                                                | The slot type: <code>physical</code> or <code>logical</code>                                                                                                                                                                                                                                                                                                                                       |
| <code>datoid</code>              | <code>oid</code> (references <code>pg_database.oid</code> )      | The OID of the database this slot is associated with, or null. Only logical slots have an associated database.                                                                                                                                                                                                                                                                                     |
| <code>database</code>            | <code>name</code> (references <code>pg_database.datname</code> ) | The name of the database this slot is associated with, or null. Only logical slots have an associated database.                                                                                                                                                                                                                                                                                    |
| <code>temporary</code>           | <code>bool</code>                                                | True if this is a temporary replication slot. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.                                                                                                                                                                                                                                       |
| <code>active</code>              | <code>bool</code>                                                | True if this slot is currently being streamed                                                                                                                                                                                                                                                                                                                                                      |
| <code>active_pid</code>          | <code>int4</code>                                                | The process ID of the session streaming data for this slot. <code>NULL</code> if inactive.                                                                                                                                                                                                                                                                                                         |
| <code>xmin</code>                | <code>xid</code>                                                 | The oldest transaction that this slot needs the database to retain. <code>VACUUM</code> cannot remove tuples deleted by any later transaction.                                                                                                                                                                                                                                                     |
| <code>catalog_xmin</code>        | <code>xid</code>                                                 | The oldest transaction affecting the system catalogs that this slot needs the database to retain. <code>VACUUM</code> cannot remove catalog tuples deleted by any later transaction.                                                                                                                                                                                                               |
| <code>restart_lsn</code>         | <code>pg_lsn</code>                                              | The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints unless this LSN gets behind more than <code>max_slot_wal_keep_size</code> from the current LSN. <code>NULL</code> if the LSN of this slot has never been reserved.                                                                           |
| <code>confirmed_flush_lsn</code> | <code>pg_lsn</code>                                              | The address (LSN) up to which the logical slot's consumer has confirmed receiving data. Data corresponding to the transactions committed before this LSN is not available anymore. <code>NULL</code> for physical slots.                                                                                                                                                                           |
| <code>wal_status</code>          | <code>text</code>                                                | Availability of WAL files claimed by this slot. Possible values are: <ul style="list-style-type: none"> <li><code>reserved</code> means that the claimed files are within <code>max_wal_size</code>.</li> <li><code>extended</code> means that <code>max_wal_size</code> is exceeded but the files are still retained, either by the replication slot or by <code>wal_keep_size</code>.</li> </ul> |

| Column                           | Type                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                         | <ul style="list-style-type: none"> <li><b>unreserved</b> means that the slot no longer retains the required WAL files and some of them are to be removed at the next checkpoint. This typically occurs when <code>max_slot_wal_keep_size</code> is set to a non-negative value. This state can return to <b>reserved</b> or <b>extended</b>.</li> <li><b>lost</b> means that this slot is no longer usable.</li> </ul>                                                                                                                                                                                                                                                                                                  |
| <code>safe_wal_size</code>       | <code>int8</code>       | The number of bytes that can be written to WAL such that this slot is not in danger of getting in state "lost". It is NULL for lost slots, as well as if <code>max_slot_wal_keep_size</code> is -1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>two_phase</code>           | <code>bool</code>       | True if the slot is enabled for decoding prepared transactions. Always false for physical slots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>two_phase_at</code>        | <code>pg_lsn</code>     | The address (LSN) from which the decoding of prepared transactions is enabled. NULL for logical slots where <code>two_phase</code> is false and for physical slots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>inactive_since</code>      | <code>timestampz</code> | The time when the slot became inactive. NULL if the slot is currently being streamed. If the slot becomes invalid, this value will never be updated. For standby slots that are being synced from a primary server (whose <code>syncd</code> field is true), the <code>inactive_since</code> indicates the time when slot synchronization (see Section 47.2.3) was most recently stopped. NULL if the slot has always been synchronized. This helps standby slots track when synchronization was interrupted.                                                                                                                                                                                                           |
| <code>conflicting</code>         | <code>bool</code>       | True if this logical slot conflicted with recovery (and so is now invalidated). When this column is true, check <code>invalidation_reason</code> column for the conflict reason. Always NULL for physical slots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>invalidation_reason</code> | <code>text</code>       | The reason for the slot's invalidation. It is set for both logical and physical slots. NULL if the slot is not invalidated. Possible values are: <ul style="list-style-type: none"> <li><b>wal_removed</b> means that the required WAL has been removed.</li> <li><b>rows_removed</b> means that the required rows have been removed. It is set only for logical slots.</li> <li><b>wal_level_insufficient</b> means that the primary doesn't have a <code>wal_level</code> sufficient to perform logical decoding. It is set only for logical slots.</li> <li><b>idle_timeout</b> means that the slot has remained inactive longer than the configured <code>idle_replication_slot_timeout</code> duration.</li> </ul> |
| <code>failover</code>            | <code>bool</code>       | True if this is a logical slot enabled to be synced to the standbys so that logical replication can be resumed from the new primary after failover. Always false for physical slots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>syncd</code>               | <code>bool</code>       | True if this is a logical slot that was synced from a primary server. On a hot standby, the slots with the <code>syncd</code> column marked as true can neither be used for logical decoding nor dropped manually. The value of this column has no meaning on the primary server; the column value on the primary is default false for all slots but may (if leftover from a promoted standby) also be true.                                                                                                                                                                                                                                                                                                            |

## 53.21. pg\_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

**Table 53.21. pg\_roles Columns**

| Column Type                        | Description                                                                                                                |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| rolname name                       | Role name                                                                                                                  |
| rolsuper bool                      | Role has superuser privileges                                                                                              |
| rolinherit bool                    | Role automatically inherits privileges of roles it is a member of                                                          |
| rolcreaterole bool                 | Role can create more roles                                                                                                 |
| rolcreatedb bool                   | Role can create databases                                                                                                  |
| rolcanlogin bool                   | Role can log in. That is, this role can be given as the initial session authorization identifier                           |
| rolreplication bool                | Role is a replication role. A replication role can initiate replication connections and create and drop replication slots. |
| rolconnlimit int4                  | For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.       |
| rolpassword text                   | Not the password (always reads as *****)                                                                                   |
| rolvaliduntil timestamptz          | Password expiry time (only used for password authentication); null if no expiration                                        |
| rolbypassrls bool                  | Role bypasses every row-level security policy, see Section 5.9 for more information.                                       |
| rolconfig text[]                   | Role-specific defaults for run-time configuration variables                                                                |
| oid oid (references pg_authid.oid) | ID of role                                                                                                                 |

## 53.22. pg\_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

**Table 53.22. pg\_rules Columns**

| Column Type                                       | Description                                        |
|---------------------------------------------------|----------------------------------------------------|
| schemaname name (references pg_namespace.nspname) | Name of schema containing table                    |
| tablename name (references pg_class.relname)      | Name of table the rule is for                      |
| rulename name (references pg_rewrite.rulename)    | Name of rule                                       |
| definition text                                   | Rule definition (a reconstructed creation command) |

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

## 53.23. `pg_seclabels`

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

**Table 53.23. `pg_seclabels` Columns**

| Column Type                                                                | Description                                                                                                                                                                                       |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>objoid oid</code> (references any OID column)                        | The OID of the object this security label pertains to                                                                                                                                             |
| <code>classoid oid</code> (references <code>pg_class.oid</code> )          | The OID of the system catalog this object appears in                                                                                                                                              |
| <code>objsubid int4</code>                                                 | For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero. |
| <code>objtype text</code>                                                  | The type of object to which this label applies, as text.                                                                                                                                          |
| <code>objnamespace oid</code> (references <code>pg_namespace.oid</code> )  | The OID of the namespace for this object, if applicable; otherwise NULL.                                                                                                                          |
| <code>objname text</code>                                                  | The name of the object to which this label applies, as text.                                                                                                                                      |
| <code>provider text</code> (references <code>pg_seclabel.provider</code> ) | The label provider associated with this label.                                                                                                                                                    |
| <code>label text</code> (references <code>pg_seclabel.label</code> )       | The security label applied to this object.                                                                                                                                                        |

## 53.24. `pg_sequences`

The view `pg_sequences` provides access to useful information about each sequence in the database.

**Table 53.24. `pg_sequences` Columns**

| Column Type                                                                  | Description                        |
|------------------------------------------------------------------------------|------------------------------------|
| <code>schemaname name</code> (references <code>pg_namespace.nspname</code> ) | Name of schema containing sequence |
| <code>sequencename name</code> (references <code>pg_class.relname</code> )   | Name of sequence                   |
| <code>sequenceowner name</code> (references <code>pg_authid.rolname</code> ) | Name of sequence's owner           |
| <code>data_type regtype</code> (references <code>pg_type.oid</code> )        | Data type of the sequence          |
| <code>start_value int8</code>                                                | Start value of the sequence        |
| <code>min_value int8</code>                                                  | Minimum value of the sequence      |
| <code>max_value int8</code>                                                  | Maximum value of the sequence      |

| Column Type                    | Description                                                                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>increment_by int8</code> | Increment value of the sequence                                                                                                          |
| <code>cycle bool</code>        | Whether the sequence cycles                                                                                                              |
| <code>cache_size int8</code>   | Cache size of the sequence                                                                                                               |
| <code>last_value int8</code>   | The last sequence value written to disk. If caching is used, this value can be greater than the last value handed out from the sequence. |

The `last_value` column will read as null if any of the following are true:

- The sequence has not been read from yet.
- The current user does not have `USAGE` or `SELECT` privilege on the sequence.
- The sequence is unlogged and the server is a standby.

## 53.25. pg\_settings

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the `SHOW` and `SET` commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.

**Table 53.25. pg\_settings Columns**

| Column Type                  | Description                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>name text</code>       | Run-time configuration parameter name                                                                                        |
| <code>setting text</code>    | Current value of the parameter                                                                                               |
| <code>unit text</code>       | Implicit unit of the parameter                                                                                               |
| <code>category text</code>   | Logical group of the parameter                                                                                               |
| <code>short_desc text</code> | A brief description of the parameter                                                                                         |
| <code>extra_desc text</code> | Additional, more detailed, description of the parameter                                                                      |
| <code>context text</code>    | Context required to set the parameter's value (see below)                                                                    |
| <code>vartype text</code>    | Parameter type ( <code>bool</code> , <code>enum</code> , <code>integer</code> , <code>real</code> , or <code>string</code> ) |
| <code>source text</code>     | Source of the current parameter value                                                                                        |
| <code>min_val text</code>    | Minimum allowed value of the parameter (null for non-numeric values)                                                         |
| <code>max_val text</code>    | Maximum allowed value of the parameter (null for non-numeric values)                                                         |

| Column Type                       | Description                                                                                                                                                                                                                                                                                                  |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enumvals text[]</code>      | Allowed values of an enum parameter (null for non-enum values)                                                                                                                                                                                                                                               |
| <code>boot_val text</code>        | Parameter value assumed at server startup if the parameter is not otherwise set                                                                                                                                                                                                                              |
| <code>reset_val text</code>       | Value that RESET would reset the parameter to in the current session                                                                                                                                                                                                                                         |
| <code>sourcefile text</code>      | Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a user who neither is a superuser nor has privileges of <code>pg_read_all_settings</code> ); helpful when using <code>include</code> directives in configuration files |
| <code>sourceline int4</code>      | Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a user who neither is a superuser nor has privileges of <code>pg_read_all_settings</code> ).                                                    |
| <code>pending_restart bool</code> | <code>true</code> if the value has been changed in the configuration file but needs a restart; or <code>false</code> otherwise.                                                                                                                                                                              |

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

#### `internal`

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

#### `postmaster`

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower `context` types can also be set at server start time.

#### `sighup`

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the SIGHUP signal to its child processes so that they all pick up the new value.

#### `superuser-backend`

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable), but only if the connecting user is a superuser or has been granted the appropriate `SET` privilege. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

#### `backend`

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable); any user can make such a change for their ses-

sion. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

#### superuser

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers and users with the appropriate `SET` privilege can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

#### user

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change their session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See Section 19.1 for more information about the various ways to change these parameters.

This view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

This view does not display customized options unless the extension module that defines them has been loaded by the backend process executing the query (e.g., via a mention in `shared_preload_libraries`, a call to a C function in the extension, or the `LOAD` command). For example, since archive modules are normally loaded only by the archiver process not regular sessions, this view will not display any customized options defined by such modules unless special action is taken to load them into the backend process executing the query.

## 53.26. pg\_shadow

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

**Table 53.26. pg\_shadow Columns**

| Column Type                                                             | Description                                                                           |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <code>username name</code> (references <code>pg_authid.rolname</code> ) | User name                                                                             |
| <code>usesysid oid</code> (references <code>pg_authid.oid</code> )      | ID of this user                                                                       |
| <code>usecreatedb bool</code>                                           | User can create databases                                                             |
| <code>usesuper bool</code>                                              | User is a superuser                                                                   |
| <code>userepl bool</code>                                               | User can initiate streaming replication and put the system in and out of backup mode. |
| <code>usebypassrpls bool</code>                                         | User bypasses every row-level security policy, see Section 5.9 for more information.  |

| Column Type                       | Description                                                                                                     |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>passwd text</code>          | Encrypted password; null if none. See <code>pg_authid</code> for details of how encrypted passwords are stored. |
| <code>valuntil timestamptz</code> | Password expiry time (only used for password authentication)                                                    |
| <code>useconfig text[]</code>     | Session defaults for run-time configuration variables                                                           |

## 53.27. `pg_shmem_allocations`

The `pg_shmem_allocations` view shows allocations made from the server's main shared memory segment. This includes both memory allocated by PostgreSQL itself and memory allocated by extensions using the mechanisms detailed in Section 36.10.11.

Note that this view does not include memory allocated using the dynamic shared memory infrastructure.

**Table 53.27. `pg_shmem_allocations` Columns**

| Column Type                      | Description                                                                                                                                                                                                                                                                                                |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name text</code>           | The name of the shared memory allocation. NULL for unused memory and <code>&lt;anonymous&gt;</code> for anonymous allocations.                                                                                                                                                                             |
| <code>off int8</code>            | The offset at which the allocation starts. NULL for anonymous allocations, since details related to them are not known.                                                                                                                                                                                    |
| <code>size int8</code>           | Size of the allocation in bytes                                                                                                                                                                                                                                                                            |
| <code>allocated_size int8</code> | Size of the allocation in bytes including padding. For anonymous allocations, no information about padding is available, so the <code>size</code> and <code>allocated_size</code> columns will always be equal. Padding is not meaningful for free memory, so the columns will be equal in that case also. |

Anonymous allocations are allocations that have been made with `ShmemAlloc()` directly, rather than via `ShmemInitStruct()` or `ShmemInitHash()`.

By default, the `pg_shmem_allocations` view can be read only by superusers or roles with privileges of the `pg_read_all_stats` role.

## 53.28. `pg_shmem_allocations_numa`

The `pg_shmem_allocations_numa` shows how shared memory allocations in the server's main shared memory segment are distributed across NUMA nodes. This includes both memory allocated by PostgreSQL itself and memory allocated by extensions using the mechanisms detailed in Section 36.10.11. This view will output multiple rows for each of the shared memory segments provided that they are spread across multiple NUMA nodes. This view should not be queried by monitoring systems as it is very slow and may end up allocating shared memory in case it was not used earlier. Current limitation for this view is that won't show anonymous shared memory allocations.

Note that this view does not include memory allocated using the dynamic shared memory infrastructure.

**Warning**

When determining the NUMA node, the view touches all memory pages for the shared memory segment. This will force allocation of the shared memory, if it wasn't allocated already, and the memory may get allocated in a single NUMA node (depending on system configuration).

**Table 53.28. pg\_shmem\_allocations\_numa Columns**

| Column Type    | Description                                                         |
|----------------|---------------------------------------------------------------------|
| name text      | The name of the shared memory allocation.                           |
| numa_node int4 | ID of NUMA node                                                     |
| size int8      | Size of the allocation on this particular NUMA memory node in bytes |

By default, the `pg_shmem_allocations_numa` view can be read only by superusers or roles with privileges of the `pg_read_all_stats` role.

## 53.29. pg\_stats

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

**Table 53.29. pg\_stats Columns**

| Column Type                                       | Description                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schemaname name (references pg_namespace.nspname) | Name of schema containing table                                                                                                                                                                                                                                                                                                                                                |
| tablename name (references pg_class.relname)      | Name of table                                                                                                                                                                                                                                                                                                                                                                  |
| attname name (references pg_attribute.attname)    | Name of column described by this row                                                                                                                                                                                                                                                                                                                                           |
| inherited bool                                    | If true, this row includes values from child tables, not just the values in the specified table                                                                                                                                                                                                                                                                                |
| null_frac float4                                  | Fraction of column entries that are null                                                                                                                                                                                                                                                                                                                                       |
| avg_width int4                                    | Average width in bytes of column's entries                                                                                                                                                                                                                                                                                                                                     |
| n_distinct float4                                 | If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have |

| Column Type                                               | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                           | a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.                                                                                                                                                                                                                                   |
| <code>most_common_vals</code> <code>anyarray</code>       | A list of the most common values in the column. (Null if no values seem to be more common than any others.)                                                                                                                                                                                                                                                                               |
| <code>most_common_freqs</code> <code>float4[]</code>      | A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)                                                                                                                                                                                                                   |
| <code>histogram_bounds</code> <code>anyarray</code>       | A list of values that divide the column's values into groups of approximately equal population. The values in <code>most_common_vals</code> , if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a < operator or if the <code>most_common_vals</code> list accounts for the entire population.)                          |
| <code>correlation</code> <code>float4</code>              | Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a < operator.)              |
| <code>most_common_elems</code> <code>anyarray</code>      | A list of non-null element values most often appearing within values of the column. (Null for scalar types.)                                                                                                                                                                                                                                                                              |
| <code>most_common_elem_freqs</code> <code>float4[]</code> | A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.) |
| <code>elem_count_histogram</code> <code>float4[]</code>   | A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)                                                                                                                                                                                                     |
| <code>range_length_histogram</code> <code>anyarray</code> | A histogram of the lengths of non-empty and non-null range values of a range type column. (Null for non-range types.)<br>This histogram is calculated using the <code>subtype_diff</code> range function regardless of whether range bounds are inclusive.                                                                                                                                |
| <code>range_empty_frac</code> <code>float4</code>         | Fraction of column entries whose values are empty ranges. (Null for non-range types.)                                                                                                                                                                                                                                                                                                     |
| <code>range_bounds_histogram</code> <code>anyarray</code> | A histogram of lower and upper bounds of non-empty and non-null range values. (Null for non-range types.)<br>These two histograms are represented as a single array of ranges, whose lower bounds represent the histogram of lower bounds, and upper bounds represent the histogram of upper bounds.                                                                                      |

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

## 53.30. pg\_stats\_ext

The view `pg_stats_ext` provides access to information about each extended statistics object in the database, combining information stored in the `pg_statistic_ext` and `pg_statistic_ext_data` catalogs. This view allows access only to rows of `pg_statistic_ext` and `pg_statistic_ext_data` that correspond to tables the user owns, and therefore it is safe to allow public read access to this view.

`pg_stats_ext` is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever new types of extended statistics are added to `pg_statistic_ext`.

**Table 53.30. `pg_stats_ext` Columns**

| Column Type                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <code>inherited bool</code> (references <code>pg_statistic_ext_data.stxdinherit</code> ) | If true, the stats include values from child tables, not just the values in the specified relation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>n_distinct pg_ndistinct</code>                                                     | N-distinct counts for combinations of column values. If greater than zero, the estimated number of distinct values in the combination. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique combination of columns in which the number of distinct combinations is the same as the number of rows. |

| Column Type | Description                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | A list of the base frequencies of the most common combinations, i.e., product of per-value frequencies. (Null when <code>most_common_vals</code> is.) |

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

## 53.31. `pg_stats_ext_exprs`

The view `pg_stats_ext_exprs` provides access to information about all expressions included in extended statistics objects, combining information stored in the `pg_statistic_ext` and `pg_statistic_ext_data` catalogs. This view allows access only to rows of `pg_statistic_ext` and `pg_statistic_ext_data` that correspond to tables the user owns, and therefore it is safe to allow public read access to this view.

`pg_stats_ext_exprs` is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever the structure of statistics in `pg_statistic_ext` changes.

**Table 53.31. `pg_stats_ext_exprs` Columns**

| Column Type                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <code>expr text</code>                                                                   | Expression included in the extended statistics object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>inherited bool</code> (references <code>pg_statistic_ext_data.stxdinherit</code> ) | If true, the stats include values from child tables, not just the values in the specified relation                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>null_frac float4</code>                                                            | Fraction of expression entries that are null                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>avg_width int4</code>                                                              | Average width in bytes of expression's entries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>n_distinct float4</code>                                                           | If greater than zero, the estimated number of distinct values in the expression. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the expression seems to have a fixed number of possible values.) For example, -1 indicates a unique expression in which the number of distinct values is the same as the number of rows. |
| <code>most_common_vals anyarray</code>                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Column Type                                  | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | A list of the most common values in the expression. (Null if no values seem to be more common than any others.)                                                                                                                                                                                                                                                                                |
| <code>most_common_freqs float4[]</code>      | A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)                                                                                                                                                                                                                        |
| <code>histogram_bounds anyarray</code>       | A list of values that divide the expression's values into groups of approximately equal population. The values in <code>most_common_vals</code> , if present, are omitted from this histogram calculation. (This expression is null if the expression data type does not have a < operator or if the <code>most_common_vals</code> list accounts for the entire population.)                   |
| <code>correlation float4</code>              | Statistical correlation between physical row ordering and logical ordering of the expression values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the expression will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This expression is null if the expression's data type does not have a < operator.) |
| <code>most_common_elems anyarray</code>      | A list of non-null element values most often appearing within values of the expression. (Null for scalar types.)                                                                                                                                                                                                                                                                               |
| <code>most_common_elem_freqs float4[]</code> | A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.)      |
| <code>elem_count_histogram float4[]</code>   | A histogram of the counts of distinct non-null element values within the values of the expression, followed by the average number of distinct non-null elements. (Null for scalar types.)                                                                                                                                                                                                      |

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

## 53.32. pg\_tables

The view `pg_tables` provides access to useful information about each table in the database.

**Table 53.32. pg\_tables Columns**

| Column Type                                                                   | Description                                                        |
|-------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <code>schemaname name</code> (references <code>pg_namespace.nspname</code> )  | Name of schema containing table                                    |
| <code>tablename name</code> (references <code>pg_class.relname</code> )       | Name of table                                                      |
| <code>tableowner name</code> (references <code>pg_authid.rolname</code> )     | Name of table's owner                                              |
| <code>tablespace name</code> (references <code>pg_tablespace.spcname</code> ) | Name of tablespace containing table (null if default for database) |
| <code>hasindexes bool</code> (references <code>pg_class.relhasindex</code> )  |                                                                    |

| Column Type                                           | Description                                     |
|-------------------------------------------------------|-------------------------------------------------|
|                                                       | True if table has (or recently had) any indexes |
| hasrules bool (references pg_class.relhasrules)       | True if table has (or once had) rules           |
| hastriggers bool (references pg_class.relhastriggers) | True if table has (or once had) triggers        |
| rowsecurity bool (references pg_class.relrowsecurity) | True if row security is enabled on the table    |

## 53.33. pg\_timezone\_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `TimeZone` or `timezone_abbreviations` run-time parameters are modified.

**Table 53.33. pg\_timezone\_abbrevs Columns**

| Column Type         | Description                                        |
|---------------------|----------------------------------------------------|
| abbrev text         | Time zone abbreviation                             |
| utc_offset interval | Offset from UTC (positive means east of Greenwich) |
| is_dst bool         | True if this is a daylight-savings abbreviation    |

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.4 for more information). In such cases this view presents their current meaning.

## 53.34. pg\_timezone\_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 53.34. pg\_timezone\_names Columns**

| Column Type         | Description                                        |
|---------------------|----------------------------------------------------|
| name text           | Time zone name                                     |
| abbrev text         | Time zone abbreviation                             |
| utc_offset interval | Offset from UTC (positive means east of Greenwich) |
| is_dst bool         | True if currently observing daylight savings       |

## 53.35. pg\_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

**Table 53.35. pg\_user Columns**

| Column Type                       | Description                                                                           |
|-----------------------------------|---------------------------------------------------------------------------------------|
| <code>username name</code>        | User name                                                                             |
| <code>usesysid oid</code>         | ID of this user                                                                       |
| <code>usecreatedb bool</code>     | User can create databases                                                             |
| <code>usesuper bool</code>        | User is a superuser                                                                   |
| <code>userepl bool</code>         | User can initiate streaming replication and put the system in and out of backup mode. |
| <code>usebypassrls bool</code>    | User bypasses every row-level security policy, see Section 5.9 for more information.  |
| <code>passwd text</code>          | Not the password (always reads as <code>*****</code> )                                |
| <code>valuntil timestamptz</code> | Password expiry time (only used for password authentication)                          |
| <code>useconfig text[]</code>     | Session defaults for run-time configuration variables                                 |

## 53.36. pg\_user\_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the `options` field if the user has no rights to use it.

**Table 53.36. pg\_user\_mappings Columns**

| Column Type                                                      | Description                                                               |
|------------------------------------------------------------------|---------------------------------------------------------------------------|
| <code>umid oid (references pg_user_mapping.oid)</code>           | OID of the user mapping                                                   |
| <code>srvid oid (references pg_foreign_server.oid)</code>        | The OID of the foreign server that contains this mapping                  |
| <code>srvname name (references pg_foreign_server.srvname)</code> | Name of the foreign server                                                |
| <code>umuser oid (references pg_authid.oid)</code>               | OID of the local role being mapped, or zero if the user mapping is public |
| <code>username name</code>                                       | Name of the local user to be mapped                                       |
| <code>umoptions text[]</code>                                    | User mapping specific options, as “keyword=value” strings                 |

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

## 53.37. pg\_views

The view `pg_views` provides access to useful information about each view in the database.

**Table 53.37. pg\_views Columns**

| Column Type                                                                  | Description                                                 |
|------------------------------------------------------------------------------|-------------------------------------------------------------|

| <code>definition text</code>                                                 | View definition (a reconstructed <code>SELECT</code> query) |

## 53.38. pg\_wait\_events

The view `pg_wait_events` provides description about the wait events.

**Table 53.38. pg\_wait\_events Columns**

| Column Type                   | Description            |
|-------------------------------|------------------------|
| <code>type text</code>        | Wait event type        |
| <code>name text</code>        | Wait event name        |
| <code>description text</code> | Wait event description |

---

# Chapter 54. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.2 of the protocol, introduced in PostgreSQL version 18. The server and the libpq client library are backwards compatible with protocol version 3.0, implemented in PostgreSQL 7.4 and later.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

## 54.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as **NOTIFY**) where-in the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as **COPY**.

### 54.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

## 54.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: *prepared statements* and *portals*. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for *parameters*. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For `SELECT` statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-`SELECT` statements.)

The overall execution cycle consists of a *parse* step, which creates a prepared statement from a textual query string; a *bind* step, which creates a portal given a prepared statement and values for any needed parameters; and an *execute* step that runs a portal's query. In the case of a query that returns rows (`SELECT`, `SHOW`, etc.), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

## 54.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different *formats*. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a *format code*. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

## 54.1.4. Protocol Versions

The current, latest version of the protocol is version 3.2. However, for backwards compatibility with old server versions and middleware that don't support the version negotiation yet, libpq still uses protocol version 3.0 by default.

A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g., the client requests version 3.2,

but the server supports only 3.0), the server may either reject the connection or may respond with a `NegotiateProtocolVersion` message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

The protocol negotiation was introduced in PostgreSQL version 9.3.21. Earlier versions would reject the connection if the client requested a minor version that was not supported by the server.

Table 54.1 shows the currently supported protocol versions.

**Table 54.1. Protocol Versions**

| Version | Supported by             | Description                                                                                                                                                                                                                                                                                  |
|---------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3.2     | PostgreSQL 18 and later  | Current latest version. The secret key used in query cancellation was enlarged from 4 bytes to a variable length field. The <code>BackendKeyData</code> message was changed to accommodate that, and the <code>CancelRequest</code> message was redefined to have a variable length payload. |
| 3.1     | -                        | Reserved. Version 3.1 has not been used by any PostgreSQL version, but it was skipped because old versions of the popular <code>pgbouncer</code> application had a bug in the protocol negotiation which made it incorrectly claim that it supported version 3.1.                            |
| 3.0     | PostgreSQL 7.4 and later |                                                                                                                                                                                                                                                                                              |
| 2.0     | up to PostgreSQL 13      | See previous releases of the PostgreSQL documentation for details                                                                                                                                                                                                                            |

## 54.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 54.7.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, `COPY`, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

### 54.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as `pg_hba.conf`) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI, SSPI and SASL, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For

GSSAPI, SSPI and SASL, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

#### ErrorResponse

The connection attempt has been rejected. The server then immediately closes the connection.

#### AuthenticationOk

The authentication exchange is successfully completed.

#### AuthenticationKerberosV5

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.

#### AuthenticationCleartextPassword

The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.

#### AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

### Warning

Support for MD5-encrypted passwords is deprecated and will be removed in a future release of PostgreSQL. Refer to Section 20.5 for details about migrating to another password type.

#### AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a GSSResponse message with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

#### AuthenticationSSPI

The frontend must now initiate an SSPI negotiation. The frontend will send a GSSResponse with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

#### AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the

GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another GSSResponse message. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

#### AuthenticationSASL

The frontend must now initiate a SASL negotiation, using one of the SASL mechanisms listed in the message. The frontend will send a SASLInitialResponse with the name of the selected mechanism, and the first part of the SASL data stream in response to this. If further messages are needed, the server will respond with AuthenticationSASLContinue. See Section 54.3 for details.

#### AuthenticationSASLContinue

This message contains challenge data from the previous step of SASL negotiation (AuthenticationSASL, or a previous AuthenticationSASLContinue). The frontend must respond with a SASL-Response message.

#### AuthenticationSASLFinal

SASL authentication has completed with additional mechanism-specific data for the client. The server will next send AuthenticationOk to indicate successful authentication, or an ErrorResponse to indicate failure. This message is sent only if the SASL mechanism specifies additional data to be sent from server to client at completion.

#### NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e., beginning with `_pq_`.) in the startup packet.

After this message, the authentication will continue using the version indicated by the server. If the client does not support the older version, it should immediately close the connection. If the server does not send this message, it supports the client's requested protocol version and all the protocol options.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

#### BackendKeyData

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

The PostgreSQL server will always send this message, but some third party backend implementations of the protocol that don't support query cancellation are known not to.

**ParameterStatus**

This message informs the frontend about the current (initial) setting of backend parameters, such as `client_encoding` or `DateStyle`. The frontend can ignore this message, or record the settings for its future use; see Section 54.2.7 for more details. The frontend should not respond to this message, but should continue listening for a `ReadyForQuery` message.

**ReadyForQuery**

Start-up is completed. The frontend can now issue commands.

**ErrorResponse**

Start-up failed. The connection is closed after sending this message.

**NoticeResponse**

A warning message has been issued. The frontend should display the message but continue listening for `ReadyForQuery` or `ErrorResponse`.

The `ReadyForQuery` message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider `ReadyForQuery` as starting a command cycle, or to consider `ReadyForQuery` as ending the start-up phase and each subsequent command cycle.

## 54.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a `Query` message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a `ReadyForQuery` response message. `ReadyForQuery` informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for `ReadyForQuery` before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

**CommandComplete**

An SQL command completed normally.

**CopyInResponse**

The backend is ready to copy data from the frontend to a table; see Section 54.2.6.

**CopyOutResponse**

The backend is ready to copy data from a table to the frontend; see Section 54.2.6.

**RowDescription**

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc. query. The contents of this message describe the column layout of the rows. This will be followed by a `DataRow` message for each row being returned to the frontend.

**DataRow**

One of the set of rows returned by a `SELECT`, `FETCH`, etc. query.

**EmptyQueryResponse**

An empty query string was recognized.

**ErrorResponse**

An error has occurred.

**ReadyForQuery**

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a **SELECT** query (or other queries that return row sets, such as **EXPLAIN** or **SHOW**) normally consists of RowDescription, zero or more DataRow messages, and then CommandComplete. **COPY** to or from the frontend invokes special protocol as described in Section 54.2.6. All other query types normally produce only a CommandComplete message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is EmptyQueryResponse followed by ReadyForQuery.

In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a **FETCH** from a cursor declared with the **BINARY** option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 54.2.7 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 54.2.2.1. Multiple Statements in a Simple Query

When a simple Query message contains more than one SQL statement (separated by semicolons), those statements are executed as a single transaction, unless explicit transaction control commands are included to force a different behavior. For example, if the message contains

```
INSERT INTO mytable VALUES(1);  
SELECT 1/0;  
INSERT INTO mytable VALUES(2);
```

then the divide-by-zero failure in the **SELECT** will force rollback of the first **INSERT**. Furthermore, because execution of the message is abandoned at the first error, the second **INSERT** is never attempted at all.

If instead the message contains

```
BEGIN;  
INSERT INTO mytable VALUES(1);  
COMMIT;  
INSERT INTO mytable VALUES(2);  
SELECT 1/0;
```

then the first **INSERT** is committed by the explicit **COMMIT** command. The second **INSERT** and the **SELECT** are still treated as a single transaction, so that the divide-by-zero failure will roll back the second **INSERT**, but not the first one.

This behavior is implemented by running the statements in a multi-statement Query message in an *implicit transaction block* unless there is some explicit transaction block for them to run in. The main difference between an implicit transaction block and a regular one is that an implicit block is closed automatically at the end of the Query message, either by an implicit commit if there was no error, or an implicit rollback if there was an error. This is similar to the implicit commit or rollback that happens for a statement executed by itself (when not in a transaction block).

If the session is already in a transaction block, as a result of a **BEGIN** in some previous message, then the Query message simply continues that transaction block, whether the message contains one statement or several. However, if the Query message contains a **COMMIT** or **ROLLBACK** closing the existing transaction block, then any following statements are executed in an implicit transaction block. Conversely, if a **BEGIN** appears in a multi-statement Query message, then it starts a regular transaction block that will only be terminated by an explicit **COMMIT** or **ROLLBACK**, whether that appears in this Query message or a later one. If the **BEGIN** follows some statements that were executed as an implicit transaction block, those statements are not immediately committed; in effect, they are retroactively included into the new regular transaction block.

A **COMMIT** or **ROLLBACK** appearing in an implicit transaction block is executed as normal, closing the implicit block; however, a warning will be issued since a **COMMIT** or **ROLLBACK** without a previous **BEGIN** might represent a mistake. If more statements follow, a new implicit transaction block will be started for them.

Savepoints are not allowed in an implicit transaction block, since they would conflict with the behavior of automatically closing the block upon any error.

Remember that, regardless of any transaction control commands that may be present, execution of the Query message stops at the first error. Thus for example given

```
BEGIN;  
SELECT 1/0;  
ROLLBACK;
```

in a single Query message, the session will be left inside a failed regular transaction block, since the **ROLLBACK** is not reached after the divide-by-zero error. Another **ROLLBACK** will be needed to restore the session to a usable state.

Another behavior of note is that initial lexical and syntactic analysis is done on the entire query string before any of it is executed. Thus simple errors (such as a misspelled keyword) in later statements can prevent execution of any of the statements. This is normally invisible to users since the statements would all roll back anyway when done as an implicit transaction block. However, it can be visible when attempting to do multiple transactions within a multi-statement Query. For instance, if a typo turned our previous example into

```
BEGIN;  
INSERT INTO mytable VALUES(1);  
COMMIT;  
INSERT INTO mytable VALUES(2);  
SELCT 1/0;
```

then none of the statements would get run, resulting in the visible difference that the first `INSERT` is not committed. Errors detected at semantic analysis or later, such as a misspelled table or column name, do not have this effect.

Lastly, note that all the statements within the Query message will observe the same value of `statement_timestamp()`, since that timestamp is updated only upon receipt of the Query message. This will result in them all observing the same value of `transaction_timestamp()` as well, except in cases where the query string ends a previously-started transaction and begins a new one.

### 54.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

#### Note

A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols (`$n`) used in the query string. Another special case is that a parameter's type can be specified as `void` (that is, the OID of the `void` pseudo-type). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if `$3` and `$4` are specified as having type `void`.

#### Note

The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the

Parse message, pass NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either BindComplete or ErrorResponse.

### Note

The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The **BINARY** attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using **DECLARE CURSOR** and **FETCH**.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn't cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a PortalSuspended message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The CommandComplete message indicating completion of the source SQL command is not sent until the portal's execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it's not inside a **BEGIN/COMMIT** transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected *while* processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

### Note

Sync does not cause a transaction block opened with **BEGIN** to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

### Tip

In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

### Note

The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

## 54.2.4. Pipelining

Use of the extended query protocol allows *pipelining*, which means sending a series of queries without waiting for earlier ones to complete. This reduces the number of network round trips needed to complete a given series of operations. However, the user must carefully consider the required behavior if one of the steps fails, since later queries will already be in flight to the server.

One way to deal with that is to make the whole query series be a single transaction, that is wrap it in **BEGIN ... COMMIT**. However, this does not help if one wishes for some of the commands to commit independently of others.

The extended query protocol provides another way to manage this concern, which is to omit sending Sync messages between steps that are dependent. Since, after an error, the backend will skip command messages until it finds Sync, this allows later commands in a pipeline to be skipped automatically when an earlier one fails, without the client having to manage that explicitly with **BEGIN** and **COMMIT**. Independently-committable segments of the pipeline can be separated by Sync messages.

If the client has not issued an explicit **BEGIN**, then an implicit transaction block is started and each **Sync** ordinarily causes an implicit **COMMIT** if the preceding step(s) succeeded, or an implicit **ROLL - BACK** if they failed. This implicit transaction block will only be detected by the server when the first command ends without a **sync**. There are a few DDL commands (such as **CREATE DATABASE**) that cannot be executed inside a transaction block. If one of these is executed in a pipeline, it will fail unless it is the first command after a **Sync**. Furthermore, upon success it will force an immediate commit to preserve database consistency. Thus a **Sync** immediately following one of these commands has no effect except to respond with **ReadyForQuery**.

When using this method, completion of the pipeline must be determined by counting **ReadyForQuery** messages and waiting for that to reach the number of **Syncs** sent. Counting command completion responses is unreliable, since some of the commands may be skipped and thus not produce a completion message.

## 54.2.5. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's `pg_proc` system catalog. The client must have `execute` permission for the function.

### Note

The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does **SELECT function(\$1, ...)**. The Function Call cycle can then be replaced with **Bind/Execute**.

A Function Call cycle is initiated by the frontend sending a **FunctionCall** message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a **ReadyForQuery** response message. **ReadyForQuery** informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

**ErrorResponse**

An error has occurred.

**FunctionCallResponse**

The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

**ReadyForQuery**

Processing of the function call is complete. **ReadyForQuery** will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

## 54.2.6. COPY Operations

The **COPY** command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a `CopyInResponse` message to the frontend. The frontend should then send zero or more `CopyData` messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a `CopyDone` message (allowing successful termination) or a `CopyFail` message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either `CommandComplete` (if successful) or `ErrorResponse` (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a `CopyFail` message), the backend will issue an `ErrorResponse` message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a `Sync` message is received, then it will issue `ReadyForQuery` and return to normal processing. If the `COPY` command was issued in a simple Query message, the rest of that message is discarded and `ReadyForQuery` is issued. In either case, any subsequent `CopyData`, `CopyDone`, or `CopyFail` messages issued by the frontend will simply be dropped.

The backend will ignore `Flush` and `Sync` messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for `Flush` and `Sync` is for the convenience of client libraries that always send `Flush` or `Sync` after an `Execute` message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a `CopyOutResponse` message to the frontend, followed by zero or more `CopyData` messages (always one per row), followed by `CopyDone`. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends `CommandComplete`. The frontend cannot abort the transfer (except by closing the connection or issuing a `Cancel` request), but it can discard unwanted `CopyData` and `CopyDone` messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an `ErrorResponse` message and revert to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy-out mode.

It is possible for `NoticeResponse` and `ParameterStatus` messages to be interspersed between `CopyData` messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 54.2.7). Otherwise, any message type other than `CopyData` or `CopyDone` may be treated as terminating copy-out mode.

There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to *and* from the server. Copy-both mode is initiated when a backend in walsender mode executes a `START_REPLICATION` statement. The backend sends a `CopyBothResponse` message to the frontend. Both the backend and the frontend may then send `CopyData` messages until either end sends a `CopyDone` message. After the client sends a `CopyDone` message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more `CopyData` messages. Similarly, when the server sends a `CopyDone` message, the connection goes into copy-in mode, and the server may not send any more `CopyData` messages. After both sides have sent a `CopyDone` message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode, the backend will issue an `ErrorResponse` message, discard frontend messages until a `Sync` message is received, and then issue `ReadyForQuery` and return to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy in both directions; no `CopyDone` should be sent in this case. See Section 54.4 for more information on the subprotocol transmitted over copy-both mode.

The `CopyInResponse`, `CopyOutResponse` and `CopyBothResponse` messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given `COPY` operation will use the same format, but the message design does not assume this.)

## 54.2.7. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend's command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a SET SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated. They are:

|                                            |                                          |
|--------------------------------------------|------------------------------------------|
| <code>application_name</code>              | <code>scram_iterations</code>            |
| <code>client_encoding</code>               | <code>search_path</code>                 |
| <code>DateStyle</code>                     | <code>server_encoding</code>             |
| <code>default_transaction_read_only</code> | <code>server_version</code>              |
| <code>in_hot_standby</code>                | <code>session_authorization</code>       |
| <code>integer_datetimes</code>             | <code>standard_conforming_strings</code> |
| <code>IntervalStyle</code>                 | <code>TimeZone</code>                    |
| <code>is_superuser</code>                  |                                          |

(`default_transaction_read_only` and `in_hot_standby` were not reported by releases before 14; `scram_iterations` was not reported by releases before 16; `search_path` was not reported by releases before 18.) Note that `server_version`, `server_encoding` and `integer_datetimes` are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same channel name.

### Note

At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before Ready-ForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

## 54.2.8. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don't want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a `CancelRequest` message, rather than the `StartupMessage` message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A `CancelRequest` message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

## 54.2.9. Termination

The normal, graceful termination procedure is that the frontend sends a `Terminate` message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn't want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-`SELECT` query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (`BEGIN ... COMMIT` sequence) then its results might be committed before the disconnection is recognized.

## 54.2.10. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 18.9.

To initiate an SSL-encrypted connection, the frontend initially sends an `SSLRequest` message rather than a `StartupMessage`. The server then responds with a single byte containing S or N, indicating that

it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after S, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after N, send the usual StartupMessage and proceed without encryption. (Alternatively, it is permissible to issue a GSSAPIRequest message after an N response to try to use GSSAPI encryption instead of SSL.)

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. The frontend should not display this error message to the user/application, since the server has not been authenticated (CVE-2024-10977<sup>1</sup>). In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

When SSL encryption can be performed, the server is expected to send only the single S byte and then wait for the frontend to initiate an SSL handshake. If additional bytes are available to read at this point, it likely means that a man-in-the-middle is attempting to perform a buffer-stuffing attack (CVE-2021-23222<sup>2</sup>). Frontends should be coded either to read exactly one byte from the socket before turning the socket over to their SSL library, or to treat it as a protocol violation if they find they have read additional bytes.

Likewise the server expects the client to not begin the SSL negotiation until it receives the server's single byte response to the SSL request. If the client begins the SSL negotiation immediately without waiting for the server response to be received it can reduce connection latency by one round-trip. However this comes at the cost of not being able to handle the case where the server sends a negative response to the SSL request. In that case instead of continuing with either GSSAPI or an unencrypted connection or a protocol error the server will simply disconnect.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

A second alternate way to initiate SSL encryption is available. The server will recognize connections which immediately begin SSL negotiation without any previous SSLRequest packets. Once the SSL connection is established the server will expect a normal startup-request packet and continue negotiation over the encrypted channel. In this case any other requests for encryption will be refused. This method is not preferred for general purpose tools as it cannot negotiate the best connection encryption available or handle unencrypted connections. However it is useful for environments where both the server and client are controlled together. In that case it avoids one round trip of latency and allows the use of network tools that depend on standard SSL connections. When using SSL connections in this style the client is required to use the ALPN extension defined by RFC 7301<sup>3</sup> to protect against protocol confusion attacks. The PostgreSQL protocol is "postgresql" as registered at IANA TLS ALPN Protocol IDs<sup>4</sup> registry.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

## 54.2.11. GSSAPI Session Encryption

If PostgreSQL was built with GSSAPI support, frontend/backend communications can be encrypted using GSSAPI. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with GSSAPI, see Section 18.10.

To initiate a GSSAPI-encrypted connection, the frontend initially sends a GSSAPIRequest message rather than a StartupMessage. The server then responds with a single byte containing G or N, indicating that it is willing or unwilling to perform GSSAPI encryption, respectively. The frontend might

---

<sup>1</sup> <https://www.postgresql.org/support/security/CVE-2024-10977/>

<sup>2</sup> <https://www.postgresql.org/support/security/CVE-2021-23222/>

<sup>3</sup> <https://tools.ietf.org/html/rfc7301>

<sup>4</sup> <https://www.iana.org/assignments/tls-extensiontype-values/tls-extensiontype-values.xhtml#alpn-protocol-ids>

close the connection at this point if it is dissatisfied with the response. To continue after G, using the GSSAPI C bindings as discussed in RFC 2744<sup>5</sup> or equivalent, perform a GSSAPI initialization by calling `gss_init_sec_context()` in a loop and sending the result to the server, starting with an empty input and then with each result from the server, until it returns no output. When sending the results of `gss_init_sec_context()` to the server, prepend the length of the message as a four byte integer in network byte order. To continue after N, send the usual StartupMessage and proceed without encryption. (Alternatively, it is permissible to issue an SSLRequest message after an N response to try to use SSL encryption instead of GSSAPI.)

The frontend should also be prepared to handle an ErrorMessage response to GSSENCRequest from the server. The frontend should not display this error message to the user/application, since the server has not been authenticated (CVE-2024-10977<sup>6</sup>). In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting GSSAPI encryption.

When GSSAPI encryption can be performed, the server is expected to send only the single G byte and then wait for the frontend to initiate a GSSAPI handshake. If additional bytes are available to read at this point, it likely means that a man-in-the-middle is attempting to perform a buffer-stuffing attack (CVE-2021-23222<sup>7</sup>). Frontends should be coded either to read exactly one byte from the socket before turning the socket over to their GSSAPI library, or to treat it as a protocol violation if they find they have read additional bytes.

An initial GSSENCRequest can also be used in a connection that is being opened to send a Cancel-Request message.

Once GSSAPI encryption has been successfully established, use `gss_wrap()` to encrypt the usual StartupMessage and all subsequent data, prepending the length of the result from `gss_wrap()` as a four byte integer in network byte order to the actual encrypted payload. Note that the server will only accept encrypted packets from the client which are less than 16kB; `gss_wrap_size_limit()` should be used by the client to determine the size of the unencrypted message which will fit within this limit and larger messages should be broken up into multiple `gss_wrap()` calls. Typical segments are 8kB of unencrypted data, resulting in encrypted packets of slightly larger than 8kB but well within the 16kB maximum. The server can be expected to not send encrypted packets of larger than 16kB to the client.

While the protocol itself does not provide a way for the server to force GSSAPI encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

## 54.3. SASL Authentication

SASL is a framework for authentication in connection-oriented protocols. At the moment, PostgreSQL implements three SASL authentication mechanisms: SCRAM-SHA-256, SCRAM-SHA-256-PLUS, and OAUTHBEARER. More might be added in the future. The below steps illustrate how SASL authentication is performed in general, while the next subsections give more details on particular mechanisms.

### SASL Authentication Message Flow

1. To begin a SASL authentication exchange, the server sends an AuthenticationSASL message. It includes a list of SASL authentication mechanisms that the server can accept, in the server's preferred order.
2. The client selects one of the supported mechanisms from the list, and sends a SASLInitialResponse message to the server. The message includes the name of the selected mechanism, and an optional Initial Client Response, if the selected mechanism uses that.

---

<sup>5</sup> <https://datatracker.ietf.org/doc/html/rfc2744>

<sup>6</sup> <https://www.postgresql.org/support/security/CVE-2024-10977/>

<sup>7</sup> <https://www.postgresql.org/support/security/CVE-2021-23222/>

3. One or more server-challenge and client-response message will follow. Each server-challenge is sent in an `AuthenticationSASLContinue` message, followed by a response from client in a `SASLResponse` message. The particulars of the messages are mechanism specific.
4. Finally, when the authentication exchange is completed successfully, the server sends an optional `AuthenticationSASLFinal` message, followed immediately by an `AuthenticationOk` message. The `AuthenticationSASLFinal` contains additional server-to-client data, whose content is particular to the selected authentication mechanism. If the authentication mechanism doesn't use additional data that's sent at completion, the `AuthenticationSASLFinal` message is not sent.

On error, the server can abort the authentication at any stage, and send an `ErrorMessage`.

### 54.3.1. SCRAM-SHA-256 Authentication

SCRAM-SHA-256, and its variant with channel binding `SCRAM-SHA-256-PLUS`, are password-based authentication mechanisms. They are described in detail in RFC 7677<sup>8</sup> and RFC 5802<sup>9</sup>.

When SCRAM-SHA-256 is used in PostgreSQL, the server will ignore the user name that the client sends in the `client-first-message`. The user name that was already sent in the startup message is used instead. PostgreSQL supports multiple character encodings, while SCRAM dictates UTF-8 to be used for the user name, so it might be impossible to represent the PostgreSQL user name in UTF-8.

The SCRAM specification dictates that the password is also in UTF-8, and is processed with the `SASLprep` algorithm. PostgreSQL, however, does not require UTF-8 to be used for the password. When a user's password is set, it is processed with `SASLprep` as if it was in UTF-8, regardless of the actual encoding used. However, if it is not a legal UTF-8 byte sequence, or it contains UTF-8 byte sequences that are prohibited by the `SASLprep` algorithm, the raw password will be used without `SASLprep` processing, instead of throwing an error. This allows the password to be normalized when it is in UTF-8, but still allows a non-UTF-8 password to be used, and doesn't require the system to know which encoding the password is in.

*Channel binding* is supported in PostgreSQL builds with SSL support. The SASL mechanism name for SCRAM with channel binding is `SCRAM-SHA-256-PLUS`. The channel binding type used by PostgreSQL is `tls-server-end-point`.

In SCRAM without channel binding, the server chooses a random number that is transmitted to the client to be mixed with the user-supplied password in the transmitted password hash. While this prevents the password hash from being successfully retransmitted in a later session, it does not prevent a fake server between the real server and client from passing through the server's random value and successfully authenticating.

SCRAM with channel binding prevents such man-in-the-middle attacks by mixing the signature of the server's certificate into the transmitted password hash. While a fake server can retransmit the real server's certificate, it doesn't have access to the private key matching that certificate, and therefore cannot prove it is the owner, causing SSL connection failure.

#### Example

1. The server sends an `AuthenticationSASL` message. It includes a list of SASL authentication mechanisms that the server can accept. This will be `SCRAM-SHA-256-PLUS` and `SCRAM-SHA-256` if the server is built with SSL support, or else just the latter.
2. The client responds by sending a `SASLInitialResponse` message, which indicates the chosen mechanism, `SCRAM-SHA-256` or `SCRAM-SHA-256-PLUS`. (A client is free to choose either mechanism, but for better security it should choose the channel-binding variant if it can support it.) In the Initial Client response field, the message contains the SCRAM `client-first-`

---

<sup>8</sup> <https://datatracker.ietf.org/doc/html/rfc7677>

<sup>9</sup> <https://datatracker.ietf.org/doc/html/rfc5802>

message. The `client-first-message` also contains the channel binding type chosen by the client.

3. Server sends an `AuthenticationSASLContinue` message, with a `SCRAM server-first-message` as the content.
4. Client sends a `SASLResponse` message, with `SCRAM client-final-message` as the content.
5. Server sends an `AuthenticationSASLFinal` message, with the `SCRAM server-final-message`, followed immediately by an `AuthenticationOk` message.

## 54.3.2. OAUTHBEARER Authentication

OAUTHBEARER is a token-based mechanism for federated authentication. It is described in detail in RFC 7628<sup>10</sup>.

A typical exchange differs depending on whether or not the client already has a bearer token cached for the current user. If it does not, the exchange will take place over two connections: the first "discovery" connection to obtain OAuth metadata from the server, and the second connection to send the token after the client has obtained it. (libpq does not currently implement a caching method as part of its builtin flow, so it uses the two-connection exchange.)

This mechanism is client-initiated, like SCRAM. The client initial response consists of the standard "GS2" header used by SCRAM, followed by a list of `key=value` pairs. The only key currently supported by the server is `auth`, which contains the bearer token. OAUTHBEARER additionally specifies three optional components of the client initial response (the `authzid` of the GS2 header, and the `host` and `port` keys) which are currently ignored by the server.

OAUTHBEARER does not support channel binding, and there is no "OAUTHBEARER-PLUS" mechanism. This mechanism does not make use of server data during a successful authentication, so the `AuthenticationSASLFinal` message is not used in the exchange.

### Example

1. During the first exchange, the server sends an `AuthenticationSASL` message with the `OAUTHBEARER` mechanism advertised.
2. The client responds by sending a `SASLInitialResponse` message which indicates the `OAUTHBEARER` mechanism. Assuming the client does not already have a valid bearer token for the current user, the `auth` field is empty, indicating a discovery connection.
3. Server sends an `AuthenticationSASLContinue` message containing an error `status` alongside a well-known URI and scopes that the client should use to conduct an OAuth flow.
4. Client sends a `SASLResponse` message containing the empty set (a single `0x01` byte) to finish its half of the discovery exchange.
5. Server sends an `ErrorMessage` to fail the first exchange.

At this point, the client conducts one of many possible OAuth flows to obtain a bearer token, using any metadata that it has been configured with in addition to that provided by the server. (This description is left deliberately vague; OAUTHBEARER does not specify or mandate any particular method for obtaining a token.)

Once it has a token, the client reconnects to the server for the final exchange:

6. The server once again sends an `AuthenticationSASL` message with the `OAUTHBEARER` mechanism advertised.

---

<sup>10</sup> <https://datatracker.ietf.org/doc/html/rfc7628>

7. The client responds by sending a SASLInitialResponse message, but this time the `auth` field in the message contains the bearer token that was obtained during the client flow.
8. The server validates the token according to the instructions of the token provider. If the client is authorized to connect, it sends an AuthenticationOk message to end the SASL exchange.

## 54.4. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the `replication` parameter in the startup message. A Boolean value of `true` (or `on`, `yes`, `1`) tells the backend to go into physical replication walsender mode, wherein a small set of replication commands, shown below, can be issued instead of SQL statements.

Passing `database` as the value for the `replication` parameter instructs the backend to go into logical replication walsender mode, connecting to the database specified in the `dbname` parameter. In logical replication walsender mode, the replication commands shown below as well as normal SQL commands can be issued.

In either physical replication or logical replication walsender mode, only the simple query protocol can be used.

For the purpose of testing replication commands, you can make a replication connection via `psql` or any other libpq-using tool with a connection string including the `replication` option, e.g.:

```
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
```

However, it is often more useful to use `pg_receivewal` (for physical replication) or `pg_recvlogical` (for logical replication).

Replication commands are logged in the server log when `log_replication_commands` is enabled.

The commands accepted in replication mode are:

### IDENTIFY\_SYSTEM

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

`systemid` (text)

The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

`timeline` (int8)

Current timeline ID. Also useful to check that the standby is consistent with the primary.

`xlogpos` (text)

Current WAL flush location. Useful to get a known location in the write-ahead log where streaming can start.

`dbname` (text)

Database connected to or null.

### SHOW *name*

Requests the server to send the current setting of a run-time parameter. This is similar to the SQL command `SHOW`.

*name*

The name of a run-time parameter. Available parameters are documented in Chapter 19.

#### **TIMELINE\_HISTORY** *t li*

Requests the server to send over the timeline history file for timeline *t li*. Server replies with a result set of a single row, containing two fields. While the fields are labeled as `text`, they effectively return raw bytes, with no encoding conversion:

`filename` (`text`)

File name of the timeline history file, e.g., `00000002.history`.

`content` (`text`)

Contents of the timeline history file.

**CREATE\_REPLICATION\_SLOT** *slot\_name* [ `TEMPORARY` ] { `PHYSICAL` | `LOGICAL` *output\_plugin* } [ ( *option* [, ...] ) ]

Create a physical or logical replication slot. See Section 26.2.6 for more about replication slots.

*slot\_name*

The name of the slot to create. Must be a valid replication slot name (see Section 26.2.6.1).

*output\_plugin*

The name of the output plugin used for logical decoding (see Section 47.6).

**TEMPORARY**

Specify that this replication slot is a temporary one. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.

The following options are supported:

**TWO\_PHASE** [ *boolean* ]

If true, this logical replication slot supports decoding of two-phase commit. With this option, commands related to two-phase commit such as `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED` are decoded and transmitted. The transaction will be decoded and transmitted at `PREPARE TRANSACTION` time. The default is false.

**RESERVE\_WAL** [ *boolean* ]

If true, this physical replication slot reserves WAL immediately. Otherwise, WAL is only reserved upon connection from a streaming replication client. The default is false.

**SNAPSHOT** { `'export'` | `'use'` | `'nothing'` }

Decides what to do with the snapshot created during logical slot initialization. `'export'`, which is the default, will export the snapshot for use in other sessions. This option can't be used inside a transaction. `'use'` will use the snapshot for the current transaction executing the command. This option must be used in a transaction, and `CREATE_REPLICATION_SLOT` must be the first command run in that transaction. Finally, `'nothing'` will just use the snapshot for logical decoding as normal but won't do anything else with it.

**FAILOVER** [ *boolean* ]

If true, the slot is enabled to be synced to the standbys so that logical replication can be resumed after failover. The default is false.

In response to this command, the server will send a one-row result set containing the following fields:

`slot_name` (text)

The name of the newly-created replication slot.

`consistent_point` (text)

The WAL location at which the slot became consistent. This is the earliest location from which streaming can start on this replication slot.

`snapshot_name` (text)

The identifier of the snapshot exported by the command. The snapshot is valid until a new command is executed on this connection or the replication connection is closed. Null if the created slot is physical.

`output_plugin` (text)

The name of the output plugin used by the newly-created replication slot. Null if the created slot is physical.

```
CREATE_REPLICATION_SLOT slot_name [ TEMPORARY ] { PHYSICAL [ RESERVE_WAL ] |  
LOGICAL output_plugin [ EXPORT_SNAPSHOT | NOEXPORT_SNAPSHOT | USE_SNAPSHOT  
| TWO_PHASE ] }
```

For compatibility with older releases, this alternative syntax for the `CREATE_REPLICATION_SLOT` command is still supported.

```
ALTER_REPLICATION_SLOT slot_name ( option [, ...] )
```

Change the definition of a replication slot. See Section 26.2.6 for more about replication slots. This command is currently only supported for logical replication slots.

*slot\_name*

The name of the slot to alter. Must be a valid replication slot name (see Section 26.2.6.1).

The following options are supported:

`TWO_PHASE` [ *boolean* ]

If true, this logical replication slot supports decoding of two-phase commit. With this option, commands related to two-phase commit such as `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED` are decoded and transmitted. The transaction will be decoded and transmitted at `PREPARE TRANSACTION` time.

`FAILOVER` [ *boolean* ]

If true, the slot is enabled to be synced to the standbys so that logical replication can be resumed after failover.

```
READ_REPLICATION_SLOT slot_name
```

Read some information associated with a replication slot. Returns a tuple with NULL values if the replication slot does not exist. This command is currently only supported for physical replication slots.

In response to this command, the server will return a one-row result set, containing the following fields:

`slot_type` (text)

The replication slot's type, either `physical` or `NULL`.

`restart_lsn` (text)

The replication slot's `restart_lsn`.

`restart_tli` (int8)

The timeline ID associated with `restart_lsn`, following the current timeline history.

`START_REPLICATION [ SLOT slot_name ] [ PHYSICAL ] XXX/XXX [ TIMELINE tli ]`

Instructs server to start streaming WAL, starting at WAL location `XXX/XXX`. If `TIMELINE` option is specified, streaming starts on timeline `tli`; otherwise, the server's current timeline is selected. The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, the server responds with a `CopyBothResponse` message, and then starts to stream WAL to the frontend.

If a slot's name is provided via `slot_name`, it will be updated as replication progresses so that the server knows which WAL segments, and if `hot_standby_feedback` is on which transactions, are still needed by the standby.

If the client requests a timeline that's not the latest but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested start point up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server skips `COPY` mode entirely.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the `COPY` mode. When the client acknowledges this by also exiting `COPY` mode, the server sends a result set with one row and two columns, indicating the next timeline in this server's history. The first column is the next timeline's ID (type `int8`), and the second column is the WAL location where the switch happened (type `text`). Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends two `CommandComplete` messages (one that ends the `CopyData` and the other ends the `START_REPLICATION` itself), and is ready to accept a new command.

WAL data is sent as a series of `CopyData` messages; see Section 54.6 and Section 54.7 for details. (This allows other information to be intermixed; in particular the server can send an `ErrorResponse` message if it encounters a failure after beginning to stream.) The payload of each `CopyData` message from server to the client contains a message of one of the following formats:

`XLogData` (B)

`Byte1('w')`

Identifies the message as WAL data.

`Int64`

The starting point of the WAL data in this message.

`Int64`

The current end of WAL on the server.

`Int64`

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

**Byten**

A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

**Primary keepalive message (B)****Byte1('k')**

Identifies the message as a sender keepalive.

**Int64**

The current end of WAL on the server.

**Int64**

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

**Byte1**

1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

**Standby status update (F)****Byte1('r')**

Identifies the message as a receiver status update.

**Int64**

The location of the last WAL byte + 1 received and written to disk in the standby.

**Int64**

The location of the last WAL byte + 1 flushed to disk in the standby.

**Int64**

The location of the last WAL byte + 1 applied in the standby.

**Int64**

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

**Byte1**

If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

**Hot standby feedback message (F)****Byte1('h')**

Identifies the message as a hot standby feedback message.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Int32

The standby's current global `xmin`, excluding the `catalog_xmin` from any replication slots. If both this value and the following `catalog_xmin` are 0, this is treated as a notification that hot standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.

Int32

The epoch of the global `xmin` xid on the standby.

Int32

The lowest `catalog_xmin` of any replication slots on the standby. Set to 0 if no `catalog_xmin` exists on the standby or if hot standby feedback is being disabled.

Int32

The epoch of the `catalog_xmin` xid on the standby.

`START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [ ( option_name [ option_value ], ... ) ]`

Instructs server to start streaming WAL for logical replication, starting at either WAL location `XXX/XXX` or the slot's `confirmed_flush_lsn` (see Section 53.20), whichever is greater. This behavior makes it easier for clients to avoid updating their local LSN status when there is no data to process. However, starting at a different LSN than requested might not catch certain kinds of client errors; so the client may wish to check that `confirmed_flush_lsn` matches its expectations before issuing `START_REPLICATION`.

The server can reply with an error, for example if the slot does not exist. On success, the server responds with a `CopyBothResponse` message, and then starts to stream WAL to the frontend.

The messages inside the `CopyBothResponse` messages are of the same format documented for `START_REPLICATION ... PHYSICAL`, including two `CommandComplete` messages.

The output plugin associated with the selected slot is used to process the output for streaming.

`SLOT slot_name`

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with `CREATE_REPLICATION_SLOT` in `LOGICAL` mode.

`XXX/XXX`

The WAL location to begin streaming at.

*option\_name*

The name of an option passed to the slot's logical decoding output plugin. See Section 54.5 for options that are accepted by the standard (`pgoutput`) plugin.

*option\_value*

Optional value, in the form of a string constant, associated with the specified option.

**DROP\_REPLICATION\_SLOT** *slot\_name* [ WAIT ]

Drops a replication slot, freeing any reserved server-side resources.

*slot\_name*

The name of the slot to drop.

**WAIT**

This option causes the command to wait if the slot is active until it becomes inactive, instead of the default behavior of raising an error.

**UPLOAD\_MANIFEST**

Uploads a backup manifest in preparation for taking an incremental backup.

**BASE\_BACKUP** [ ( *option* [, ...] ) ]

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

**LABEL** '*label*'

Sets the label of the backup. If none is specified, a backup label of `base backup` will be used. The quoting rules for the label are the same as a standard SQL string with `standard_conforming_strings` turned on.

**TARGET** '*target*'

Tells the server where to send the backup. If the target is `client`, which is the default, the backup data is sent to the client. If it is `server`, the backup data is written to the server at the pathname specified by the `TARGET_DETAIL` option. If it is `blackhole`, the backup data is not sent anywhere; it is simply discarded.

The `server` target requires superuser privilege or being granted the `pg_write_server_files` role.

**TARGET\_DETAIL** '*detail*'

Provides additional information about the backup target.

Currently, this option can only be used when the backup target is `server`. It specifies the server directory to which the backup should be written.

**PROGRESS** [ *boolean* ]

If set to true, request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and might as such have a negative impact on the performance. In particular, it might take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and might both grow and shrink between the time of approximation and the sending of the actual files. The default is false.

**CHECKPOINT** { '*fast*' | '*spread*' }

Sets the type of checkpoint to be performed at the beginning of the base backup. The default is `spread`.

**WAL** [ *boolean* ]

If set to true, include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the `pg_wal` directory of the base directory tar file. The default is false.

**WAIT** [ *boolean* ]

If set to true, the backup will wait until the last required WAL segment has been archived, or emit a warning if WAL archiving is not enabled. If false, the backup will neither wait nor warn, leaving the client responsible for ensuring the required log is available. The default is true.

**COMPRESSION** '*method*'

Instructs the server to compress the backup using the specified method. Currently, the supported methods are `gzip`, `lz4`, and `zstd`.

**COMPRESSION\_DETAIL** *detail*

Specifies details for the chosen compression method. This should only be used in conjunction with the **COMPRESSION** option. If the value is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form *keyword* or *keyword=value*. Currently, the supported keywords are `level`, `long` and `workers`.

The `level` keyword sets the compression level. For `gzip` the compression level should be an integer between 1 and 9 (default `Z_DEFAULT_COMPRESSION` or -1), for `lz4` an integer between 1 and 12 (default 0 for fast compression mode), and for `zstd` an integer between `ZSTD_minCLevel()` (usually -131072) and `ZSTD_maxCLevel()` (usually 22), (default `ZSTD_CLEVEL_DEFAULT` or 3).

The `long` keyword enables long-distance matching mode, for improved compression ratio, at the expense of higher memory use. Long-distance mode is supported only for `zstd`.

The `workers` keyword sets the number of threads that should be used for parallel compression. Parallel compression is supported only for `zstd`.

**MAX\_RATE** *rate*

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

**TABLESPACE\_MAP** [ *boolean* ]

If true, include information about symbolic links present in the directory `pg_tblspc` in a file named `tablespace_map`. The tablespace map file includes each symbolic link name as it exists in the directory `pg_tblspc/` and the full path of that symbolic link. The default is false.

**VERIFY\_CHECKSUMS** [ *boolean* ]

If true, checksums are verified during a base backup if they are enabled. If false, this is skipped. The default is true.

**MANIFEST** *manifest\_option*

When this option is specified with a value of `yes` or `force-encode`, a backup manifest is created and sent along with the backup. The manifest is a list of every file present in the backup with the exception of any WAL files that may be included. It also stores the size, last modification time, and optionally a checksum for each file. A value of `force-encode`

forces all filenames to be hex-encoded; otherwise, this type of encoding is performed only for files whose names are non-UTF8 octet sequences. `force-encode` is intended primarily for testing purposes, to be sure that clients which read the backup manifest can handle this case. For compatibility with previous releases, the default is `MANIFEST 'no'`.

#### `MANIFEST_CHECKSUMS checksum_algorithm`

Specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are `NONE`, `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`. The default is `CRC32C`.

#### `INCREMENTAL`

Requests an incremental backup. The `UPLOAD_MANIFEST` command must be executed before running a base backup with this option.

When the backup is started, the server will first send two ordinary result sets, followed by one or more `CopyOutResponse` results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in `XLogRecPtr` format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

`spcoid` (`oid`)

The OID of the tablespace, or null if it's the base directory.

`spcllocation` (`text`)

The full path of the tablespace directory, or null if it's the base directory.

`size` (`int8`)

The approximate size of the tablespace, in kilobytes (1024 bytes), if progress report has been requested; otherwise it's null.

After the second regular result set, a `CopyOutResponse` will be sent. The payload of each `Copy-Data` message will contain a message in one of the following formats:

`new archive` (`B`)

`Byte1('n')`

Identifies the message as indicating the start of a new archive. There will be one archive for the main data directory and one for each additional tablespace; each will use tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard).

`String`

The file name for this archive.

`String`

For the main data directory, an empty string. For other tablespaces, the full path to the directory from which this archive was created.

`manifest` (`B`)

`Byte1('m')`

Identifies the message as indicating the start of the backup manifest.

archive or manifest data (B)

Byte1('d')

Identifies the message as containing archive or manifest data.

Byte $n$

Data bytes.

progress report (B)

Byte1('p')

Identifies the message as a progress report.

Int64

The number of bytes from the current tablespace for which processing has been completed.

After the CopyOutResponse, or all such responses, have been sent, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- `pg_internal.init` (found in multiple directories)
- Various temporary files and directories created during the operation of the PostgreSQL server, such as any file or directory beginning with `pgsql_tmp` and temporary relations.
- Unlogged relations, except for the init fork which is required to recreate the (empty) unlogged relation on recovery.
- `pg_wal`, including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_wal` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_dynshmem`, `pg_notify`, `pg_repslot`, `pg_serial`, `pg_snapshots`, `pg_stat_tmp`, and `pg_subtrans` are copied as empty directories (even if they are symbolic links).
- Files other than regular files and directories, such as symbolic links (other than for the directories listed above) and special device and operating system files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group, and file mode are set if the underlying file system on the server supports it.

In all the above commands, when specifying a parameter of type `boolean` the *value* part can be omitted, which is equivalent to specifying `TRUE`.

## 54.5. Logical Streaming Replication Protocol

This section describes the logical replication protocol, which is the message flow started by the `START_REPLICATION SLOT slot_name LOGICAL` replication command.

The logical streaming replication protocol builds on the primitives of the physical streaming replication protocol.

PostgreSQL logical decoding supports output plugins. `pgoutput` is the standard one used for the built-in logical replication.

## 54.5.1. Logical Streaming Replication Parameters

Using the `START_REPLICATION` command, `pgoutput` accepts the following options:

`proto_version`

Protocol version. Currently versions 1, 2, 3, and 4 are supported. A valid version is required.

Version 2 is supported only for server version 14 and above, and it allows streaming of large in-progress transactions.

Version 3 is supported only for server version 15 and above, and it allows streaming of two-phase commits.

Version 4 is supported only for server version 16 and above, and it allows streams of large in-progress transactions to be applied in parallel.

`publication_names`

Comma-separated list of publication names for which to subscribe (receive changes). The individual publication names are treated as standard object names and can be quoted the same as needed. At least one publication name is required.

`binary`

Boolean option to use binary transfer mode. Binary mode is faster than the text mode but slightly less robust.

`messages`

Boolean option to enable sending the messages that are written by `pg_logical_emit_message`.

`streaming`

Option to enable streaming of in-progress transactions. Valid values are `off` (the default), `on` and `parallel`. The setting `parallel` enables sending extra information with some messages to be used for parallelization. Minimum protocol version 2 is required to turn it `on`. Minimum protocol version 4 is required for the `parallel` value.

`two_phase`

Boolean option to enable two-phase transactions. Minimum protocol version 3 is required to turn it `on`.

`origin`

Option to send changes by their origin. Possible values are `none` to only send the changes that have no origin associated, or `any` to send the changes regardless of their origin. This can be used to avoid loops (infinite replication of the same data) among replication nodes.

## 54.5.2. Logical Replication Protocol Messages

The individual protocol messages are discussed in the following subsections. Individual messages are described in Section 54.9.

All top-level protocol messages begin with a message type byte. While represented in code as a character, this is a signed byte with no associated encoding.

Since the streaming replication protocol supplies a message length there is no need for top-level protocol messages to embed a length in their header.

### 54.5.3. Logical Replication Protocol Message Flow

With the exception of the `START_REPLICATION` command and the replay progress messages, all information flows only from the backend to the frontend.

The logical replication protocol sends individual transactions one by one. This means that all messages between a pair of `Begin` and `Commit` messages belong to the same transaction. Similarly, all messages between a pair of `Begin Prepare` and `Prepare` messages belong to the same transaction. It also sends changes of large in-progress transactions between a pair of `Stream Start` and `Stream Stop` messages. The last stream of such a transaction contains a `Stream Commit` or `Stream Abort` message.

Every sent transaction contains zero or more DML messages (`Insert`, `Update`, `Delete`). In case of a cascaded setup it can also contain `Origin` messages. The origin message indicates that the transaction originated on different replication node. Since a replication node in the scope of logical replication protocol can be pretty much anything, the only identifier is the origin name. It's downstream's responsibility to handle this as needed (if needed). The `Origin` message is always sent before any DML messages in the transaction.

Every DML message contains a relation OID, identifying the publisher's relation that was acted on. Before the first DML message for a given relation OID, a `Relation` message will be sent, describing the schema of that relation. Subsequently, a new `Relation` message will be sent if the relation's definition has changed since the last `Relation` message was sent for it. (The protocol assumes that the client is capable of remembering this metadata for as many relations as needed.)

`Relation` messages identify column types by their OIDs. In the case of a built-in type, it is assumed that the client can look up that type OID locally, so no additional data is needed. For a non-built-in type OID, a `Type` message will be sent before the `Relation` message, to provide the type name associated with that OID. Thus, a client that needs to specifically identify the types of relation columns should cache the contents of `Type` messages, and first consult that cache to see if the type OID is defined there. If not, look up the type OID locally.

## 54.6. Message Data Types

This section describes the base data types used in messages.

`Int $n$ ( $i$ )`

An  $n$ -bit integer in network byte order (most significant byte first). If  $i$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `Int16`, `Int32(42)`.

`Int $n$ [ $k$ ]`

An array of  $k$   $n$ -bit integers, each in network byte order. The array length  $k$  is always determined by an earlier field in the message. Eg. `Int16[M]`.

`String( $s$ )`

A null-terminated string (C-style string). There is no specific length limitation on strings. If  $s$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `String`, `String("user")`.

#### Note

*There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don't fit into your fixed-size buffer.*

Byte $n$ ( $c$ )

Exactly  $n$  bytes. If the field width  $n$  is not a constant, it is always determinable from an earlier field in the message. If  $c$  is specified it is the exact value. Eg. Byte2, Byte1("\n").

## 54.7. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, most messages are defined so that the message end can be found without reference to the byte count. This is for historical reasons, as the original, now-obsolete protocol version 2 did not have an explicit length field. It also aids validity checking though.

AuthenticationOk (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(0)

Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(2)

Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(3)

Specifies that a clear-text password is required.

AuthenticationMD5Password (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(12)

Length of message contents in bytes, including self.

Int32(5)

Specifies that an MD5-encrypted password is required.

Byte4

The salt to use when encrypting the password.

AuthenticationGSS (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(7)

Specifies that GSSAPI authentication is required.

AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte $n$

GSSAPI or SSPI authentication data.

AuthenticationSSPI (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(9)

Specifies that SSPI authentication is required.

AuthenticationSASL (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(10)

Specifies that SASL authentication is required.

The message body is a list of SASL authentication mechanisms, in the server's order of preference. A zero byte is required as terminator after the last authentication mechanism name. For each mechanism, there is the following:

String

Name of a SASL authentication mechanism.

AuthenticationSASLContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(11)

Specifies that this message contains a SASL challenge.

Byte $n$

SASL data, specific to the SASL mechanism being used.

AuthenticationSASLFinal (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(12)

Specifies that SASL authentication has completed.

Byte $n$

SASL outcome "additional data", specific to the SASL mechanism being used.

BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

**Byte $n$** 

The secret key of this backend. This field extends to the end of the message, indicated by the length field.

The minimum and maximum key length are 4 and 256 bytes, respectively. The PostgreSQL server only sends keys up to 32 bytes, but the larger maximum size allows for future server versions, as well as connection poolers and other middleware, to use longer keys. One possible use case is augmenting the server's key with extra information. Middleware is therefore also encouraged to not use up all of the bytes, in case multiple middleware applications are layered on top of each other, each of which may wrap the key with extra data.

Before protocol version 3.2, the secret key was always 4 bytes long.

**Bind (F)****Byte1('B')**

Identifies the message as a Bind command.

**Int32**

Length of message contents in bytes, including self.

**String**

The name of the destination portal (an empty string selects the unnamed portal).

**String**

The name of the source prepared statement (an empty string selects the unnamed prepared statement).

**Int16**

The number of parameter format codes that follow (denoted  $C$  below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

**Int16[ $C$ ]**

The parameter format codes. Each must presently be zero (text) or one (binary).

**Int16**

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

**Int32**

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

**Byte $n$** 

The value of the parameter, in the format indicated by the associated format code.  $n$  is the above length.

After the last parameter, the following fields appear:

**Int16**

The number of result-column format codes that follow (denoted  $R$  below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

**Int16[ $R$ ]**

The result-column format codes. Each must presently be zero (text) or one (binary).

**BindComplete (B)****Byte1('2')**

Identifies the message as a Bind-complete indicator.

**Int32(4)**

Length of message contents in bytes, including self.

**CancelRequest (F)****Int32**

Length of message contents in bytes, including self.

**Int32(80877102)**

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

**Int32**

The process ID of the target backend.

**Byte $n$** 

The secret key for the target backend. This field extends to the end of the message, indicated by the length field. The maximum key length is 256 bytes.

Before protocol version 3.2, the secret key was always 4 bytes long.

**Close (F)****Byte1('C')**

Identifies the message as a Close command.

**Int32**

Length of message contents in bytes, including self.

**Byte1**

'S' to close a prepared statement; or 'P' to close a portal.

**String**

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

**CloseComplete (B)****Byte1('3')**

Identifies the message as a Close-complete indicator.

**Int32(4)**

Length of message contents in bytes, including self.

**CommandComplete (B)****Byte1('C')**

Identifies the message as a command-completed response.

**Int32**

Length of message contents in bytes, including self.

**String**

The command tag. This is usually a single word that identifies which SQL command was completed.

For an **INSERT** command, the tag is **INSERT *oid* *rows***, where *rows* is the number of rows inserted. *oid* used to be the object ID of the inserted row if *rows* was 1 and the target table had OIDs, but OIDs system columns are not supported anymore; therefore *oid* is always 0.

For a **DELETE** command, the tag is **DELETE *rows*** where *rows* is the number of rows deleted.

For an **UPDATE** command, the tag is **UPDATE *rows*** where *rows* is the number of rows updated.

For a **MERGE** command, the tag is **MERGE *rows*** where *rows* is the number of rows inserted, updated, or deleted.

For a **SELECT** or **CREATE TABLE AS** command, the tag is **SELECT *rows*** where *rows* is the number of rows retrieved.

For a **MOVE** command, the tag is **MOVE *rows*** where *rows* is the number of rows the cursor's position has been changed by.

For a **FETCH** command, the tag is **FETCH *rows*** where *rows* is the number of rows that have been retrieved from the cursor.

For a **COPY** command, the tag is **COPY *rows*** where *rows* is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

**CopyData (F & B)****Byte1('d')**

Identifies the message as **COPY** data.

**Int32**

Length of message contents in bytes, including self.

**Byte*n***

Data that forms part of a **COPY** data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

**CopyDone (F & B)****Byte1('c')**

Identifies the message as a **COPY**-complete indicator.

**Int32(4)**

Length of message contents in bytes, including self.

**CopyFail (F)****Byte1('f')**

Identifies the message as a **COPY**-failure indicator.

**Int32**

Length of message contents in bytes, including self.

**String**

An error message to report as the cause of failure.

**CopyInResponse (B)****Byte1('G')**

Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

**Int32**

Length of message contents in bytes, including self.

**Int8**

0 indicates the overall **COPY** format is textual (rows separated by newlines, columns separated by separator characters, etc.). 1 indicates the overall copy format is binary (similar to DataRow format). See **COPY** for more information.

**Int16**

The number of columns in the data to be copied (denoted *N* below).

**Int16[*N*]**

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

**CopyOutResponse (B)****Byte1('H')**

Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc.). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1('W')

Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc.). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)

Byte1('D')

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

Int16

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte $n$

The value of the column, in the format indicated by the associated format code.  $n$  is the above length.

Describe (F)

Byte1('D')

Identifies the message as a Describe command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to describe a prepared statement; or 'P' to describe a portal.

String

The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

EmptyQueryResponse (B)

Byte1('I')

Identifies the message as a response to an empty query string. (This substitutes for CommandComplete.)

Int32(4)

Length of message contents in bytes, including self.

ErrorResponse (B)

Byte1('E')

Identifies the message as an error.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 54.8. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

**Execute (F)****Byte1('E')**

Identifies the message as an Execute command.

**Int32**

Length of message contents in bytes, including self.

**String**

The name of the portal to execute (an empty string selects the unnamed portal).

**Int32**

Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

**Flush (F)****Byte1('H')**

Identifies the message as a Flush command.

**Int32(4)**

Length of message contents in bytes, including self.

**FunctionCall (F)****Byte1('F')**

Identifies the message as a function call.

**Int32**

Length of message contents in bytes, including self.

**Int32**

Specifies the object ID of the function to call.

**Int16**The number of argument format codes that follow (denoted *C* below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.**Int16[*C*]**

The argument format codes. Each must presently be zero (text) or one (binary).

**Int16**

Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

**Int32**

The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

**Byte $n$** 

The value of the argument, in the format indicated by the associated format code.  $n$  is the above length.

After the last argument, the following field appears:

**Int16**

The format code for the function result. Must presently be zero (text) or one (binary).

**FunctionCallResponse (B)****Byte1('V')**

Identifies the message as a function call result.

**Int32**

Length of message contents in bytes, including self.

**Int32**

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

**Byte $n$** 

The value of the function result, in the format indicated by the associated format code.  $n$  is the above length.

**GSSENCRequest (F)****Int32(8)**

Length of message contents in bytes, including self.

**Int32(80877104)**

The GSSAPI Encryption request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5680 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

**GSSResponse (F)****Byte1('p')**

Identifies the message as a GSSAPI or SSPI response. Note that this is also used for SASL and password response messages. The exact message type can be deduced from the context.

**Int32**

Length of message contents in bytes, including self.

**Byte $n$** 

GSSAPI/SSPI specific message data.

**NegotiateProtocolVersion (B)****Byte1('v')**

Identifies the message as a protocol version negotiation message.

Int32

Length of message contents in bytes, including self.

Int32

Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32

Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String

The option name.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 54.8. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

NotificationResponse (B)

Byte1('A')

Identifies the message as a notification response.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of the notifying backend process.

String

The name of the channel that the notify has been raised on.

String

The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')

Identifies the message as a parameter description.

Int32

Length of message contents in bytes, including self.

Int16

The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')

Identifies the message as a run-time parameter status report.

Int32

Length of message contents in bytes, including self.

String

The name of the run-time parameter being reported.

String

The current value of the parameter.

Parse (F)

Byte1('P')

Identifies the message as a Parse command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String

The query string to be parsed.

Int16

The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI, SSPI and SASL response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message's row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.

String

The query string itself.

ReadyForQuery (B)

Byte1('Z')

Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

Int32(5)

Length of message contents in bytes, including self.

Byte1

Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

RowDescription (B)

Byte1('T')

Identifies the message as a row description.

Int32

Length of message contents in bytes, including self.

Int16

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String

The field name.

Int32

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32

The object ID of the field's data type.

Int16

The data type size (see `pg_type.typelen`). Note that negative values denote variable-width types.

Int32

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SASLInitialResponse (F)

Byte1('p')

Identifies the message as an initial SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type is deduced from the context.

Int32

Length of message contents in bytes, including self.

String

Name of the SASL authentication mechanism that the client selected.

Int32

Length of SASL mechanism specific "Initial Client Response" that follows, or -1 if there is no Initial Response.

Byte $n$

SASL mechanism specific "Initial Response".

SASLResponse (F)

Byte1('p')

Identifies the message as a SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte $n$

SASL mechanism specific message data.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196610)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (2 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. `user` is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

`user`

The database user name to connect as. Required; there is no default.

`database`

The database to connect to. Defaults to the user name.

`options`

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (`\`); write `\\` to represent a literal backslash.

`replication`

Used to connect in streaming replication mode, where a small set of replication commands can be issued instead of SQL statements. Value can be `true`, `false`, or `database`, and the default is `false`. See Section 54.4 for details.

In addition to the above, other parameters may be listed. Parameter names beginning with `_pq_` are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

String

The parameter value.

Sync (F)

Byte1('S')

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

Terminate (F)

Byte1('X')

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

## 54.8. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

V

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message). This is identical to the S field except that the contents are never localized. This is present only in messages generated by PostgreSQL versions 9.6 and later.

C

Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.

M

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

D

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

p

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

q

Internal query: the text of a failed internally-generated command. This could be, for example, an SQL query issued by a PL/pgSQL function.

W

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

S

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

t

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table's schema.)

c

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

d

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type's schema.)

n

Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren't created with constraint syntax.)

F

File: the file name of the source-code location where the error was reported.

L

Line: the line number of the source-code location where the error was reported.

R

Routine: the name of the source-code routine reporting the error.

**Note**

The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

## 54.9. Logical Replication Message Formats

This section describes the detailed format of each logical replication message. These messages are either returned by the replication slot SQL interface or are sent by a walsender. In the case of a walsender, they are encapsulated inside replication protocol WAL messages as described in Section 54.4, and generally obey the same message flow as physical replication.

**Begin****Byte1('B')**

Identifies the message as a begin message.

**Int64 (XLogRecPtr)**

The final LSN of the transaction.

**Int64 (TimestampTz)**

Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

**Int32 (TransactionId)**

Xid of the transaction.

**Message****Byte1('M')**

Identifies the message as a logical decoding message.

**Int32 (TransactionId)**

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

**Int8**

Flags; Either 0 for no flags or 1 if the logical decoding message is transactional.

**Int64 (XLogRecPtr)**

The LSN of the logical decoding message.

**String**

The prefix of the logical decoding message.

**Int32**

Length of the content.

**Byte $n$** 

The content of the logical decoding message.

**Commit****Byte1('C')**

Identifies the message as a commit message.

**Int8(0)**

Flags; currently unused.

**Int64 (XLogRecPtr)**

The LSN of the commit.

Int64 (XLogRecPtr)

The end LSN of the transaction.

Int64 (TimestampTz)

Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Origin

Byte1('O')

Identifies the message as an origin message.

Int64 (XLogRecPtr)

The LSN of the commit on the origin server.

String

Name of the origin.

Note that there can be multiple Origin messages inside a single transaction.

Relation

Byte1('R')

Identifies the message as a relation message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the relation.

String

Namespace (empty string for `pg_catalog`).

String

Relation name.

Int8

Replica identity setting for the relation (same as `relreplident` in `pg_class`).

Int16

Number of columns.

Next, the following message part appears for each column included in the publication:

Int8

Flags for the column. Currently can be either 0 for no flags or 1 which marks the column as part of the key.

**String**

Name of the column.

**Int32 (Oid)**

OID of the column's data type.

**Int32**

Type modifier of the column (`atttypmod`).

**Type****Byte1('Y')**

Identifies the message as a type message.

**Int32 (TransactionId)**

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

**Int32 (Oid)**

OID of the data type.

**String**

Namespace (empty string for `pg_catalog`).

**String**

Name of the data type.

**Insert****Byte1('I')**

Identifies the message as an insert message.

**Int32 (TransactionId)**

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

**Int32 (Oid)**

OID of the relation corresponding to the ID in the relation message.

**Byte1('N')**

Identifies the following `TupleData` message as a new tuple.

**TupleData**

`TupleData` message part representing the contents of new tuple.

**Update****Byte1('U')**

Identifies the message as an update message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is optional and is only present if the update changed data in any of the column(s) that are part of the REPLICA IDENTITY index.

Byte1('O')

Identifies the following TupleData submessage as an old tuple. This field is optional and is only present if table in which the update happened has REPLICA IDENTITY set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key. Only present if the previous 'O' or 'K' part is present.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of a new tuple.

The Update message may contain either a 'K' message part or an 'O' message part or neither of them, but never both of them.

Delete

Byte1('D')

Identifies the message as a delete message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is present if the table in which the delete has happened uses an index as REPLICA IDENTITY.

Byte1('O')

Identifies the following TupleData message as an old tuple. This field is present if the table in which the delete happened has REPLICA IDENTITY set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key, depending on the previous field.

The Delete message may contain either a 'K' message part or an 'O' message part, but never both of them.

#### Truncate

Byte1('T')

Identifies the message as a truncate message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32

Number of relations

Int8

Option bits for TRUNCATE: 1 for CASCADE, 2 for RESTART IDENTITY

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message. This field is repeated for each relation.

The following messages (Stream Start, Stream Stop, Stream Commit, and Stream Abort) are available since protocol version 2.

#### Stream Start

Byte1('S')

Identifies the message as a stream start message.

Int32 (TransactionId)

Xid of the transaction.

Int8

A value of 1 indicates this is the first stream segment for this XID, 0 for any other stream segment.

#### Stream Stop

Byte1('E')

Identifies the message as a stream stop message.

#### Stream Commit

Byte1('c')

Identifies the message as a stream commit message.

Int32 (TransactionId)

Xid of the transaction.

Int8(0)

Flags; currently unused.

Int64 (XLogRecPtr)

The LSN of the commit.

Int64 (XLogRecPtr)

The end LSN of the transaction.

Int64 (TimestampTz)

Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

#### Stream Abort

Byte1('A')

Identifies the message as a stream abort message.

Int32 (TransactionId)

Xid of the transaction.

Int32 (TransactionId)

Xid of the subtransaction (will be same as xid of the transaction for top-level transactions).

Int64 (XLogRecPtr)

The LSN of the abort operation, present only when streaming is set to parallel. This field is available since protocol version 4.

Int64 (TimestampTz)

Abort timestamp of the transaction, present only when streaming is set to parallel. The value is in number of microseconds since PostgreSQL epoch (2000-01-01). This field is available since protocol version 4.

The following messages (Begin Prepare, Prepare, Commit Prepared, Rollback Prepared, Stream Prepare) are available since protocol version 3.

#### Begin Prepare

Byte1('b')

Identifies the message as the beginning of a prepared transaction message.

Int64 (XLogRecPtr)

The LSN of the prepare.

Int64 (XLogRecPtr)

The end LSN of the prepared transaction.

Int64 (TimestampTz)

Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)

Xid of the transaction.

String

The user defined GID of the prepared transaction.

Prepare

Byte1('P')

Identifies the message as a prepared transaction message.

Int8(0)

Flags; currently unused.

Int64 (XLogRecPtr)

The LSN of the prepare.

Int64 (XLogRecPtr)

The end LSN of the prepared transaction.

Int64 (TimestampTz)

Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)

Xid of the transaction.

String

The user defined GID of the prepared transaction.

Commit Prepared

Byte1('K')

Identifies the message as the commit of a prepared transaction message.

Int8(0)

Flags; currently unused.

Int64 (XLogRecPtr)

The LSN of the commit of the prepared transaction.

Int64 (XLogRecPtr)

The end LSN of the commit of the prepared transaction.

Int64 (TimestampTz)

Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)

Xid of the transaction.

String

The user defined GID of the prepared transaction.

**Rollback Prepared****Byte1('r')**

Identifies the message as the rollback of a prepared transaction message.

**Int8(0)**

Flags; currently unused.

**Int64 (XLogRecPtr)**

The end LSN of the prepared transaction.

**Int64 (XLogRecPtr)**

The end LSN of the rollback of the prepared transaction.

**Int64 (TimestampTz)**

Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

**Int64 (TimestampTz)**

Rollback timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

**Int32 (TransactionId)**

Xid of the transaction.

**String**

The user defined GID of the prepared transaction.

**Stream Prepare****Byte1('p')**

Identifies the message as a stream prepared transaction message.

**Int8(0)**

Flags; currently unused.

**Int64 (XLogRecPtr)**

The LSN of the prepare.

**Int64 (XLogRecPtr)**

The end LSN of the prepared transaction.

**Int64 (TimestampTz)**

Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

**Int32 (TransactionId)**

Xid of the transaction.

String

The user defined GID of the prepared transaction.

The following message parts are shared by the above messages.

TupleData

Int16

Number of columns.

Next, one of the following submessages appears for each published column:

Byte1('n')

Identifies the data as NULL value.

Or

Byte1('u')

Identifies unchanged TOASTed value (the actual value is not sent).

Or

Byte1('t')

Identifies the data as text formatted value.

Or

Byte1('b')

Identifies the data as binary formatted value.

Int32

Length of the column value.

Byten

The value of the column, either in binary or in text format. (As specified in the preceding format byte). *n* is the above length.

## 54.10. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn't a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that `PasswordMessage` now has a type byte.

`ErrorResponse` and `NoticeResponse` ('E' and 'N') messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery ('Z') message includes a transaction status indicator.

The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server's internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during text-mode COPY IN, but not in CSV mode. The text-mode behavior is deprecated and may eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus ('S') messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription ('T') message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse ('P') message is no longer generated by the backend.

The NotificationResponse ('A') message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse ('I') message used to include an empty string parameter; this has been removed.

---

# Chapter 55. PostgreSQL Coding Conventions

## 55.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc.) follow BSD conventions. In particular, curly braces for the controlled blocks of `if`, `while`, `switch`, etc. go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn't mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

To maintain a consistent coding style, do not use C++ style comments (`//` comments). `pgindent` will replace them with `/* ... */`.

The preferred style for multi-line comment blocks is

```
/*
 * comment text begins here
 * and continues here
 */
```

Note that comment blocks that begin in column 1 will be preserved as-is by `pgindent`, but it will re-flow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

```
/*-----
 * comment text begins here
 * and continues here
 *-----
 */
```

While submitted patches do not absolutely have to follow these formatting rules, it's a good idea to do so. Your code will get run through `pgindent` before the next release, so there's no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is “make the new code look like the existing code around it”.

The `src/tools/editors` directory contains sample settings files that can be used with the Emacs, xemacs or vim editors to help ensure that they format code according to these conventions.

If you'd like to run `pgindent` locally to help make your code match project style, see the `src/tools/pgindent` directory.

The text browsing tools `more` and `less` can be invoked as:

```
more -x4
less -x4
```

to make them show tabs appropriately.

## 55.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`, defined in `src/include/utils/elog.h`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec's `SQLSTATE` conventions. `ereport` itself is just a shell macro that exists mainly for the syntactic convenience of making message generation look like a single function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```
ereport(ERROR,
        errcode(ERRCODE_DIVISION_BY_ZERO),
        errmsg("division by zero"));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the `SQLSTATE` error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text.

You will also frequently see this older style, with an extra set of parentheses surrounding the auxiliary function calls:

```
ereport(ERROR,
        (errcode(ERRCODE_DIVISION_BY_ZERO),
         errmsg("division by zero")));
```

The extra parentheses were required before PostgreSQL version 12, but are now optional.

Here is a more complex example:

```
ereport(ERROR,
        errcode(ERRCODE_AMBIGUOUS_FUNCTION),
        errmsg("function %s is not unique",
               func_signature_string(funcname, nargs,
                                   NIL, actual_arg_types)),
        errhint("Unable to choose a best candidate function. "
                "You might need to add explicit typecasts.));
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided. The auxiliary function calls can be written in any order, but conventionally `errcode` and `errmsg` appear first.

If the severity level is `ERROR` or higher, `ereport` aborts execution of the current query and does not return to the caller. If the severity level is lower than `ERROR`, `ereport` returns normally.

The available auxiliary routines for `ereport` are:

- `errcode(sqlerrcode)` specifies the `SQLSTATE` error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.
- `errmsg(const char *msg, ...)` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `sprintf`-style format codes. In addition

to the standard format codes accepted by `sprintf`, the format code `%m` can be used to insert the error message returned by `strerror` for the current value of `errno`.<sup>1</sup> `%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.

- `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.
- `errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errmsg`, but with support for various plural forms of the message. *fmt\_singular* is the English singular format, *fmt\_plural* is the English plural format, *n* is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 56.2.2.
- `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.
- `errdetail_internal(const char *msg, ...)` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.
- `errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 56.2.2.
- `errdetail_log(const char *msg, ...)` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.
- `errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 56.2.2.
- `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.
- `errhint_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errhint`, but with support for various plural forms of the message. For more information see Section 56.2.2.
- `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.
- `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

---

<sup>1</sup> That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.

- `errtable(Relation rel)` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.
- `errtablecol(Relation rel, int attnum)` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.
- `errtableconstraint(Relation rel, const char *conname)` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`.
- `errdatatype(Oid datatypeOid)` specifies a data type whose name and schema name should be included as auxiliary fields in the error report.
- `errdomainconstraint(Oid datatypeOid, const char *conname)` specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.
- `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.
- `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.
- `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT :` portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.
- `errhidecontext(bool hide_ctx)` can be called to specify suppression of the `CONTEXT :` portion of a message in the postmaster log. This should only be used for verbose debugging messages where the repeated inclusion of context would bloat the log too much.

### Note

At most one of the functions `errtable`, `errtablecol`, `errtableconstraint`, `errdatatype`, or `errdomainconstraint` should be used in an `ereport` call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function `e log` that is still heavily used. An `e log` call:

```
e log(level, "format string", ...);
```

is exactly equivalent to:

```
ereport(level, errmsg_internal("format string", ...));
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, `e log` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless,

there are enough internal “cannot happen” error checks in the system that `e log` is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 55.3.

## 55.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

### What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

```
IpMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m  
(plus a long addendum that is basically a hint)
```

write:

```
Primary:    could not create shared memory segment: %m  
Detail:    Failed syscall was shmget(key=%d, size=%u, 0%o).  
Hint:      The addendum, written as a complete sentence.
```

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users aren't expected to know the details.

### Formatting

Don't put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (`\n`) can be used to indicate suggested paragraph breaks. Don't end a message with a newline. Don't use tabs or other formatting characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.

### Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should consistently use one kind of quotes that is consistent with publishing customs and computer output of other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the preferred use. Some have suggested choosing the kind of quotes depending on the type of object according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is

a language-internal technical issue that many users aren't even familiar with, it won't scale to other kinds of quoted terms, it doesn't translate to other languages, and it's pretty pointless, too.

## Use of Quotes

Always use quotes to delimit file names, user-supplied identifiers, configuration variable names, and other variables that might contain words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output as needed (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don't clutter messages with unnecessary or duplicate quote marks.

## Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they're long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there's only one sentence.

## Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.

Rationale: It's easier to make everything look more consistent this way, since some messages are complete sentences and some not.

## Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject ("A could not do B"). Use telegram style without subject if the subject would be the program itself; do not use "I" for the program.

Rationale: The program is not human. Don't pretend otherwise.

## Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

could not open file "%s": %m  
and:

cannot open file "%s"

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn't exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it's conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

## Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

## Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

## Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

could not open file %s: %m

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it's unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

## Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD:     could not open file %s  
BETTER: could not open file %s (I/O failure)

If no reason is known you better fix the code.

## Function Names

Don't include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it's not helpful information. If the error text doesn't make as much sense without the function name, reword it.

BAD: `pg_strtoint32: error in "z": cannot parse "z"`  
BETTER: `invalid input syntax for type integer: "z"`

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD: `open() failed: %m`  
BETTER: `could not open file %s: %m`

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don't know what all those functions do.

## Tricky Words to Avoid

**Unable.** “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

**Bad.** Error messages like “bad result” are really hard to interpret intelligently. It's better to write why the result is “bad”, e.g., “invalid format”.

**Illegal.** “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it's invalid.

**Unknown.** Try to avoid “unknown”. Consider “error: unknown response”. If you don't know what the response is, how do you know it's erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

BAD: `unknown node type`  
BETTER: `unrecognized node type: 42`

**Find vs. Exists.** If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn't “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn't “exist”. Using “find” in this case sounds weak and confuses the issue.

**May vs. Can vs. Might.** “May” suggests permission (e.g., “You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., “I can lift that log.”), and “might” suggests possibility (e.g., “It might rain today.”). Using the proper word clarifies meaning and assists translation.

**Contractions.** Avoid contractions, like “can't”; use “cannot” instead.

**Non-negative.** Avoid “non-negative” as it is ambiguous about whether it accepts zero. It's better to use “greater than zero” or “greater than or equal to zero”.

## Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
- parens
- auth

- `xact`

Rationale: This will improve consistency.

## Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 56.2.2 to avoid making life difficult for translators.

## 55.4. Miscellaneous Coding Conventions

### C Standard

Code in PostgreSQL should only rely on language features available in the C99 standard. That means a conforming C99 compiler has to be able to compile postgres, at least aside from a few platform dependent pieces.

A few features included in the C99 standard are, at this time, not permitted to be used in core PostgreSQL code. This currently includes variable length arrays, intermingled declarations and code, `//` comments, universal character names. Reasons for that include portability and historical practices.

Features from later revisions of the C standard or compiler specific features can be used, if a fallback is provided.

For example `_Static_assert()` and `__builtin_constant_p` are currently used, even though they are from newer revisions of the C standard and a GCC extension respectively. If not available we respectively fall back to using a C99 compatible replacement that performs the same checks, but emits rather cryptic messages and do not use `__builtin_constant_p`.

### Function-Like Macros and Inline Functions

Both macros with arguments and `static inline` functions may be used. The latter are preferable if there are multiple-evaluation hazards when written as a macro, as e.g., the case with

```
#define Max(x, y)      ((x) > (y) ? (x) : (y))
```

or when the macro would be very long. In other cases it's only possible to use macros, or at least easier. For example because expressions of various types need to be passed to the macro.

When the definition of an inline function references symbols (i.e., variables, functions) that are only available as part of the backend, the function may not be visible when included from frontend code.

```
#ifndef FRONTEND
static inline MemoryContext
MemoryContextSwitchTo(MemoryContext context)
{
    MemoryContext old = CurrentMemoryContext;

    CurrentMemoryContext = context;
    return old;
}
#endif /* FRONTEND */
```

In this example `CurrentMemoryContext`, which is only available in the backend, is referenced and the function thus hidden with a `#ifndef FRONTEND`. This rule exists because some compilers emit references to symbols contained in inline functions even if the function is not used.

## Writing Signal Handlers

To be suitable to run inside a signal handler code has to be written very carefully. The fundamental problem is that, unless blocked, a signal handler can interrupt code at any time. If code inside the signal handler uses the same state as code outside chaos may ensue. As an example consider what happens if a signal handler tries to acquire a lock that's already held in the interrupted code.

Barring special arrangements code in signal handlers may only call async-signal safe functions (as defined in POSIX) and access variables of type `volatile sig_atomic_t`. A few functions in `postgres` are also deemed signal safe, importantly `SetLatch()`.

In most cases signal handlers should do nothing more than note that a signal has arrived, and wake up code running outside of the handler using a latch. An example of such a handler is the following:

```
static void
handle_sighup(SIGNAL_ARGS)
{
    got_SIGHUP = true;
    SetLatch(MyLatch);
}
```

## Calling Function Pointers

For clarity, it is preferred to explicitly dereference a function pointer when calling the pointed-to function if the pointer is a simple variable, for example:

```
(*emit_log_hook) (edata);
```

(even though `emit_log_hook(edata)` would also work). When the function pointer is part of a structure, then the extra punctuation can and usually should be omitted, for example:

```
paramInfo->paramFetch(paramInfo, paramId);
```

---

# Chapter 56. Native Language Support

## 56.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

### 56.1.1. Requirements

We won't judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the `--enable-nls` option. This will also check for the `libintl` library and the `msgfmt` program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs `xgettext` and `msgmerge`, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won't need `xgettext`. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

### 56.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in *message catalogs*, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either `.po` or `.mo`. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are `psql.po` (PO file for `psql`) or `fr.mo` (MO file in French).

The file format of the PO files is illustrated here:

```
# comment

msgid "original string"
msgstr "translated string"

msgid "more original"
msgstr "another translated"
"string can be broken up like this"

...
```

The `msgid` lines are extracted from the program source. (They need not be, but this is the most common way.) The `msgstr` lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The `#` character introduces a comment. If whitespace immediately follows the `#` character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-whitespace character immediately following the `#`. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

```
#. automatic comment
#: filename.c:1023
#, flags, flags
```

The `#.` style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The `#:` comments indicate the exact locations where the message is used in the source. The translator need not look at the program source, but can if there is doubt about the correct translation. The `#,` comments contain flags that describe the message in some way. There are currently two flags: `fuzzy` is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is `c-format`, which indicates that the message is a `printf`-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the `c-format` flag.

### 56.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file `nls.mk`, then this program has been prepared for translation.

If there are already some `.po` files, then someone has already done some translation work. The files are named *language*.`po`, where *language* is the ISO 639-1 two-letter language code (in lower case)<sup>1</sup>, e.g., `fr.po` for French. If there is really a need for more than one translation effort per language then the files can also be named *language\_region*.`po` where *region* is the ISO 3166-1 two-letter country code (in upper case)<sup>2</sup>, e.g., `pt_BR.po` for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
make init-po
```

This will create a file *prognam*.`pot`. (`.pot` to distinguish it from PO files that are “in production”. The `T` stands for “template”.) Copy this file to *language*.`po` and edit it. To make it known that the new language is available, also edit the file `po/LINGUAS` and add the language (or language and country) code next to languages already listed, like:

```
de fr
```

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

```
make update-po
```

which will create a new blank message catalog file (the `pot` file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a `.po.new` extension.

<sup>2</sup> <https://www.iso.org/iso-3166-country-codes.html>

## 56.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. There are also several specialized editors for PO files which can help the process with translation-specific features. There is (unsurprisingly) a PO mode for Emacs, which can be quite useful.

The translator should only change the area between the quotes after the `msgstr` directive, add comments, and alter the fuzzy flag.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a `printf` format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

```
msgstr "Die Datei %2$s hat %1$u Zeichen."
```

Then the first placeholder will actually use the second argument from the list. The *digits*`$` needs to follow the `%` immediately, before any other format manipulators. (This feature really exists in the `printf` family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.
- Maintain the style and tone of the original string. Specifically, messages that are not sentences (`cannot open file %s`) should probably not start with a capital letter (if your language distinguishes letter case) or end with a period (if your language uses punctuation marks). It might help to read Section 55.3.
- If you don't know what a message means, or if it is ambiguous, ask on the developers' mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it's best to improve the message.

## 56.2. For the Programmer

### 56.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

#### Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```
#ifdef ENABLE_NLS
```

```
#include <locale.h>
#endif

...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "");
bindtextdomain("prognam", LOCALEDIR);
textdomain("prognam");
#endif
```

(The *prognam* can actually be chosen freely.)

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```
fprintf(stderr, "panic level %d\n", lvl);
```

would be changed to:

```
fprintf(stderr, gettext("panic level %d\n"), lvl);
```

(`gettext` is defined as a no-op if NLS support is not configured.)

This tends to add a lot of clutter. One common shortcut is to use:

```
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

**CATALOG\_NAME**

The program name, as provided in the `textdomain()` call.

**GETTEXT\_FILES**

List of files that contain translatable strings, i.e., those marked with `gettext` or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a `+` and the second word be a file that contains one file name per line.

**GETTEXT\_TRIGGERS**

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only `gettext()` calls are known. If you used `_` or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form `func:2` (for the second argument). If you have a function that supports pluralized messages, the item should look like `func:1,2` (identifying the singular and plural message arguments).

4. Add a file `po/LINGUAS`, which will contain the list of provided translations — initially empty.

The build system will automatically take care of building and installing the message catalogs.

## 56.2.2. Message-Writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

- Do not construct sentences at run-time, like:

```
printf("Files were %s.\n", flag ? "copied" : "removed");
```

The word order within the sentence might be different in other languages. Also, even if you remember to call `gettext()` on each fragment, the fragments might not translate well separately. It's better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

- For similar reasons, this won't work:

```
printf("copied %d file%s", n, n!=1 ? "s" : "");
```

because it assumes how the plural is formed. If you figured you could solve it like this:

```
if (n==1)
    printf("copied 1 file");
else
    printf("copied %d files", n);
```

then be disappointed. Some languages have more than two forms, with some peculiar rules. It's often best to design the message to avoid the issue altogether, for instance like this:

```
printf("number of copied files: %d", n);
```

If you really want to construct a properly pluralized message, there is support for this, but it's a bit awkward. When generating a primary or detail error message in `ereport()`, you can write something like this:

```
errmsg_plural("copied %d file",
              "copied %d files",
              n,
              n)
```

The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether *n* is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of *n*.

If you need to pluralize a message that isn't going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the `gettext` documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

```
/* translator: This message is not what it seems to be. */
```

These comments are copied to the message catalog files so that the translators can see them.

---

# Chapter 57. Writing a Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages and functions written in SQL) go through a *call handler* function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language's call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type `language_handler`. This special pseudo-type identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 36.10.

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoBaseData` struct containing argument values and information about the called function, and it is expected to return a `Datum` result (and possibly set the `isnull` field of the `FunctionCallInfoBaseData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoBaseData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It's up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-`NULL` then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoBaseData`'s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

A template for a procedural-language handler written as a C extension is provided in `src/test/modules/plsample`. This is a working sample demonstrating one way to create a procedural-language handler, process parameters, and return a value.

Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a *validator* and an *inline handler*. A validator can be provided to allow language-specific checking to be done during `CREATE FUNCTION`. An inline handler can be provided to allow the language to support anonymous code blocks executed via the `DO` command.

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator's result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a `CREATE FUNCTION` command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function's `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through `CREATE FUNCTION`. Typical checks then include verifying that the function's argument and result types are supported by the language, and that the function's body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes `SET` clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when restoring a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler's result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement's parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It's recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an *extension* so that a simple `CREATE EXTENSION` command is sufficient to install the language. See Section 36.17 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the `src/pl` subdirectory of the source tree. The `CREATE LANGUAGE` reference page also has some useful details.

---

# Chapter 58. Writing a Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the `contrib` subdirectory of the source tree. The `CREATE FOREIGN DATA WRAPPER` reference page also has some useful details.

## Note

The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn't gained wide adoption anyway.

## 58.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 36.10.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type `fdw_handler`. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 58.2.

The validator function is responsible for validating options given in `CREATE` and `ALTER` commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with. The latter corresponds to the OID of the system catalog the object would be stored in, one of:

- `AttributeRelationId`
- `ForeignDataWrapperRelationId`
- `ForeignServerRelationId`
- `ForeignTableRelationId`
- `UserMappingRelationId`

If no validator function is supplied, options are not checked at object creation time or object alteration time.

## 58.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc'd `FdwRoutine` struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The `FdwRoutine` struct type is declared in `src/include/foreign/fdwapi.h`, which see for additional details.

## 58.2.1. FDW Routines for Scanning Foreign Tables

```
void
GetForeignRelSize(PlannerInfo *root,
                  RelOptInfo *baserel,
                  Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner's global information about the query; `baserel` is the planner's information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it's passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width. (The initial value is based on column data types and on column average-width values measured by the last `ANALYZE`.) Also, this function may update `baserel->tuples` if it can compute a better estimate of the foreign table's total row count. (The initial value is from `pg_class.rel tuples` which represents the total row count seen by the last `ANALYZE`; it will be `-1` if no `ANALYZE` has been done on this foreign table.)

See Section 58.4 for additional information.

```
void
GetForeignPaths(PlannerInfo *root,
                RelOptInfo *baserel,
                Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It's recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 58.4 for additional information.

```
ForeignScan *
GetForeignPlan(PlannerInfo *root,
               RelOptInfo *baserel,
               Oid foreigntableid,
               ForeignPath *best_path,
               List *tlist,
               List *scan_clauses,
               Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths`, `GetForeignJoinPaths`, or `GetForeignUp-`

perPaths), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it's recommended to use `make_foreignscan` to build the `ForeignScan` node.

See Section 58.4 for additional information.

```
void
BeginForeignScan(ForeignScanState *node,
                 int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```
TupleTableSlot *
IterateForeignScan(ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). Return `NULL` if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that PostgreSQL's executor doesn't care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```
void
ReScanForeignScan(ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```
void
EndForeignScan(ForeignScanState *node);
```

End the scan and release resources. It is normally not important to release pallocc'd memory, but for example open files and connections to remote servers should be cleaned up.

## 58.2.2. FDW Routines for Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables' data and doing the join locally), it should provide this callback function:

```
void
GetForeignJoinPaths(PlannerInfo *root,
                    RelOptInfo *joinrel,
                    RelOptInfo *outerrel,
                    RelOptInfo *innerrel,
                    JoinType jointype,
                    JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with `GetForeignPaths`, this function should generate `ForeignPath` path(s) for the supplied `joinrel` (use `create_foreign_join_path` to build them), and call `add_path` to add these paths to the set of paths considered for the join. But unlike `GetForeignPaths`, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

Note also that the set of join clauses to apply to the join, which is passed as `extra->restrictlist`, varies depending on the combination of inner and outer relations. A `ForeignPath` path generated for the `joinrel` must contain the set of join clauses it uses, which will be used by the planner to convert the `ForeignPath` path into a plan, if it is selected by the planner as the best path for the `joinrel`.

If a `ForeignPath` path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the `scanrelid` of the resulting `ForeignScan` plan node should be set to zero, since there is no single relation that it represents; instead, the `fs_relids` field of the `ForeignScan` node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill `fdw_scan_tlist` with an appropriate list of `TargetEntry` nodes, representing the set of columns it will supply at run time in the tuples it returns.

### Note

Beginning with PostgreSQL 16, `fs_relids` includes the rangetable indexes of outer joins, if any were involved in this join. The new field `fs_base_relids` includes only base relation indexes, and thus mimics `fs_relids`'s old semantics.

See Section 58.4 for additional information.

## 58.2.3. FDW Routines for Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should provide this callback function:

```
void
```

```
GetForeignUpperPaths(PlannerInfo *root,
                     UpperRelationKind stage,
                     RelOptInfo *input_rel,
                     RelOptInfo *output_rel,
                     void *extra);
```

Create possible access paths for *upper relation* processing, which is the planner's term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate `ForeignPath` path(s) for any post-scan/join processing that the FDW knows how to perform remotely (use `create_foreign_upper_path` to build them), and call `add_path` to add these paths to the indicated upper relation. As with `GetForeignJoinPaths`, it is not necessary that this function succeed in creating any paths, since paths involving local processing are always possible.

The `stage` parameter identifies which post-scan/join step is currently being considered. `output_rel` is the upper relation that should receive paths representing computation of this step, and `input_rel` is the relation representing the input to this step. The `extra` parameter provides additional details, currently, it is set only for `UPPERREL_PARTIAL_GROUP_AGG` or `UPPERREL_GROUP_AGG`, in which case it points to a `GroupPathExtraData` structure; or for `UPPERREL_FINAL`, in which case it points to a `FinalPathExtraData` structure. (Note that `ForeignPath` paths added to `output_rel` would typically not have any direct dependency on paths of the `input_rel`, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See Section 58.4 for additional information.

## 58.2.4. FDW Routines for Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```
void
AddForeignUpdateTargets(PlannerInfo *root,
                       Index rtindex,
                       RangeTblEntry *target_rte,
                       Relation target_relation);
```

`UPDATE` and `DELETE` operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an `UPDATE` or `DELETE`.

To do that, construct a `Var` representing an extra value you need, and pass it to `add_row_identity_var`, along with a name for the junk column. (You can do this more than once if several columns are needed.) You must choose a distinct junk column name for each different `Var` you need, except that `Vars` that are identical except for the `varno` field can and should share a column name. The core system uses the junk column names `tableoid` for a table's `tableoid` column, `ctid` or `ctidW` for `ctid`, `wholerow` for a whole-row `Var` marked with `vartype = RECORD`, and `wholerowN` for a whole-row `Var` with `vartype` equal to the table's declared row type. Re-use these names when you can (the planner will combine duplicate requests for identical junk columns). If you need another kind of junk column besides these, it might be wise to choose a name prefixed with your extension name, to avoid conflicts against other FDWs.

If the `AddForeignUpdateTargets` pointer is set to `NULL`, no extra target expressions are added. (This will make it impossible to implement `DELETE` operations, though `UPDATE` may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```
List *
PlanForeignModify(PlannerInfo *root,
                  ModifyTable *plan,
                  Index resultRelation,
                  int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the `ModifyTable` plan node that performs the update action. This private information must have the form of a `List`, and will be delivered to `BeginForeignModify` during the execution stage.

`root` is the planner's global information about the query. `plan` is the `ModifyTable` plan node, which is complete except for the `fdwPrivLists` field. `resultRelation` identifies the target foreign table by its range table index. `subplan_index` identifies which target of the `ModifyTable` plan node this is, counting from zero; use this if you want to index into per-target-relation substructures of the plan node.

See Section 58.4 for additional information.

If the `PlanForeignModify` pointer is set to `NULL`, no additional plan-time actions are taken, and the `fdw_private` list delivered to `BeginForeignModify` will be `NIL`.

```
void
BeginForeignModify(ModifyTableState *mtstate,
                  ResultRelInfo *rinfo,
                  List *fdw_private,
                  int subplan_index,
                  int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor start-up. It should perform any initialization needed prior to the actual table modifications. Subsequently, `ExecForeignInsert`/`ExecForeignBatchInsert`, `ExecForeignUpdate` or `ExecForeignDelete` will be called for tuple(s) to be inserted, updated, or deleted.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.) `fdw_private` contains the private data generated by `PlanForeignModify`, if any. `subplan_index` identifies which target of the `ModifyTable` plan node this is. `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignModify` and `EndForeignModify`.

If the `BeginForeignModify` pointer is set to `NULL`, no action is taken during executor startup.

```
TupleTableSlot *
ExecForeignInsert(EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the tuple to be inserted;

it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. (The `planSlot` is typically of little interest for `INSERT` cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually inserted (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `INSERT` statement has a `RETURNING` clause or involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause or `WITH CHECK OPTION` constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignInsert` pointer is set to `NULL`, attempts to insert into the foreign table will fail with an error message.

Note that this function is also called when inserting routed tuples into a foreign-table partition or executing `COPY FROM` on a foreign table, in which case it is called in a different way than it is in the `INSERT` case. See the callback functions described below that allow the FDW to support that.

```
TupleTableSlot **
ExecForeignBatchInsert(EState *estate,
                      ResultRelInfo *rinfo,
                      TupleTableSlot **slots,
                      TupleTableSlot **planSlots,
                      int *numSlots);
```

Insert multiple tuples in bulk into the foreign table. The parameters are the same for `ExecForeignInsert` except `slots` and `planSlots` contain multiple tuples and `*numSlots` specifies the number of tuples in those arrays.

The return value is an array of slots containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions.) The passed-in `slots` can be re-used for this purpose. The number of successfully inserted tuples is returned in `*numSlots`.

The data in the returned slot is used only if the `INSERT` statement involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `WITH CHECK OPTION` constraints.

If the `ExecForeignBatchInsert` or `GetForeignModifyBatchSize` pointer is set to `NULL`, attempts to insert into the foreign table will use `ExecForeignInsert`. This function is not used if the `INSERT` has the `RETURNING` clause.

Note that this function is also called when inserting routed tuples into a foreign-table partition or executing `COPY FROM` on a foreign table, in which case it is called in a different way than it is in the `INSERT` case. See the callback functions described below that allow the FDW to support that.

```
int
GetForeignModifyBatchSize(ResultRelInfo *rinfo);
```

Report the maximum number of tuples that a single `ExecForeignBatchInsert` call can handle for the specified foreign table. The executor passes at most the given number of tuples to `ExecForeignBatchInsert`. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. The FDW is expected to provide a foreign server and/or foreign table option for the user to set this value, or some hard-coded value.

If the `ExecForeignBatchInsert` or `GetForeignModifyBatchSize` pointer is set to `NULL`, attempts to insert into the foreign table will use `ExecForeignInsert`.

```
TupleTableSlot *
ExecForeignUpdate(EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Update one tuple in the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the new data for the tuple; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan. Unlike `slot`, this tuple contains only the new values for columns changed by the query, so do not rely on attribute numbers of the foreign table to index into `planSlot`. Also, `planSlot` typically contains additional “junk” columns. In particular, any junk columns that were requested by `AddForeignUpdateTargets` will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually updated (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `UPDATE` statement has a `RETURNING` clause or involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause or `WITH CHECK OPTION` constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to `NULL`, attempts to update the foreign table will fail with an error message.

```
TupleTableSlot *
ExecForeignDelete(EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or `NULL` if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to `NULL`, attempts to delete from the foreign table will fail with an error message.

```
void
EndForeignModify(EState *estate,
```

```
ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

Tuples inserted into a partitioned table by `INSERT` or `COPY FROM` are routed to partitions. If an FDW supports routable foreign-table partitions, it should also provide the following callback functions. These functions are also called when `COPY FROM` is executed on a foreign table.

```
void  
BeginForeignInsert(ModifyTableState *mtstate,  
                  ResultRelInfo *rinfo);
```

Begin executing an insert operation on a foreign table. This routine is called right before the first tuple is inserted into the foreign table in both cases when it is the partition chosen for tuple routing and the target specified in a `COPY FROM` command. It should perform any initialization needed prior to the actual insertion. Subsequently, `ExecForeignInsert` or `ExecForeignBatchInsert` will be called for tuple(s) to be inserted into the foreign table.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.)

When this is called by a `COPY FROM` command, the plan-related global data in `mtstate` is not provided and the `planSlot` parameter of `ExecForeignInsert` subsequently called for each inserted tuple is `NULL`, whether the foreign table is the partition chosen for tuple routing or the target specified in the command.

If the `BeginForeignInsert` pointer is set to `NULL`, no action is taken for the initialization.

Note that if the FDW does not support routable foreign-table partitions and/or executing `COPY FROM` on foreign tables, this function or `ExecForeignInsert`/`ExecForeignBatchInsert` subsequently called must throw error as needed.

```
void  
EndForeignInsert(EState *estate,  
                ResultRelInfo *rinfo);
```

End the insert operation and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignInsert` pointer is set to `NULL`, no action is taken for the termination.

```
int  
IsForeignRelUpdatable(Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is,  $(1 \ll \text{CMD\_UPDATE}) = 4$  for `UPDATE`,  $(1 \ll \text{CMD\_INSERT}) = 8$  for `INSERT`, and  $(1 \ll \text{CMD\_DELETE}) = 16$  for `DELETE`.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in

the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the `information_schema` views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local structures which would affect the operation (row-level local triggers, stored generated columns, or `WITH CHECK OPTION` constraints from parent views), then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

```
bool
PlanDirectModify(PlannerInfo *root,
                  ModifyTable *plan,
                  Index resultRelation,
                  int subplan_index);
```

Decide whether it is safe to execute a direct modification on the remote server. If so, return `true` after performing planning actions needed for that. Otherwise, return `false`. This optional function is called during query planning. If this function succeeds, `BeginDirectModify`, `IteratedDirectModify` and `EndDirectModify` will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for `PlanForeignModify`.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a `ForeignScan` plan node that executes the direct modification on the remote server. The `operation` and `resultRelation` fields of the `ForeignScan` must be set appropriately. `operation` must be set to the `CmdType` enumeration corresponding to the statement kind (that is, `CMD_UPDATE` for `UPDATE`, `CMD_INSERT` for `INSERT`, and `CMD_DELETE` for `DELETE`), and the `resultRelation` argument must be copied to the `resultRelation` field.

See Section 58.4 for additional information.

If the `PlanDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
BeginDirectModify(ForeignScanState *node,
                  int eflags);
```

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to `IteratedDirectModify`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to modify is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `PlanDirectModify`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainDirectModify` and `EndDirectModify`.

If the `BeginDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
TupleTableSlot *
```

```
IterateDirectModify(ForeignScanState *node);
```

When the `INSERT`, `UPDATE` or `DELETE` query doesn't have a `RETURNING` clause, just return `NULL` after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the `RETURNING` calculation, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in `node->resultRelInfo->ri_projectReturning->pi_exprContext->ecxt_scantuple`. Return `NULL` if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginDirectModify` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the `RETURNING` calculation, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Whether the query has the clause or not, the query's reported row count must be incremented by the FDW itself. When the query doesn't have the clause, the FDW must also increment the row count for the `ForeignScanState` node in the `EXPLAIN ANALYZE` case.

If the `IterateDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void  
EndDirectModify(ForeignScanState *node);
```

Clean up following a direct modification on the remote server. It is normally not important to release `palloc'd` memory, but for example open files and connections to the remote server should be cleaned up.

If the `EndDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

## 58.2.5. FDW Routines for TRUNCATE

```
void  
ExecForeignTruncate(List *rels,  
                    DropBehavior behavior,  
                    bool restart_seqs);
```

Truncate foreign tables. This function is called when `TRUNCATE` is executed on a foreign table. `rels` is a list of `Relation` data structures of foreign tables to truncate.

`behavior` is either `DROP_RESTRICT` or `DROP_CASCADE` indicating that the `RESTRICT` or `CASCADE` option was requested in the original `TRUNCATE` command, respectively.

If `restart_seqs` is `true`, the original `TRUNCATE` command requested the `RESTART IDENTITY` behavior, otherwise the `CONTINUE IDENTITY` behavior was requested.

Note that the `ONLY` options specified in the original `TRUNCATE` command are not passed to `ExecForeignTruncate`. This behavior is similar to the callback functions of `SELECT`, `UPDATE` and `DELETE` on a foreign table.

`ExecForeignTruncate` is invoked once per foreign server for which foreign tables are to be truncated. This means that all foreign tables included in `rels` must belong to the same server.

If the `ExecForeignTruncate` pointer is set to `NULL`, attempts to truncate foreign tables will fail with an error message.

## 58.2.6. FDW Routines for Row Locking

If an FDW wishes to support *late row locking* (as described in Section 58.5), it must provide the following callback functions:

```
RowMarkType  
GetForeignRowMarkType(RangeTblEntry *rte,  
                      LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. `rte` is the `RangeTblEntry` node for the table and `strength` describes the lock strength requested by the relevant `FOR UPDATE`/`SHARE` clause, if any. The result must be a member of the `RowMarkType` enum type.

This function is called during query planning for each foreign table that appears in an `UPDATE`, `DELETE`, or `SELECT FOR UPDATE`/`SHARE` query and is not the target of `UPDATE` or `DELETE`.

If the `GetForeignRowMarkType` pointer is set to `NULL`, the `ROW_MARK_COPY` option is always used. (This implies that `RefetchForeignRow` will never be called, so it need not be provided either.)

See Section 58.5 for more information.

```
void  
RefetchForeignRow(EState *estate,  
                 ExecRowMark *erm,  
                 Datum rowid,  
                 TupleTableSlot *slot,  
                 bool *updated);
```

Re-fetch one tuple slot from the foreign table, after locking it if required. `estate` is global execution state for the query. `erm` is the `ExecRowMark` struct describing the target foreign table and the row lock type (if any) to acquire. `rowid` identifies the tuple to be fetched. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `updated` is an output parameter.

This function should store the tuple into the provided slot, or clear it if the row lock couldn't be obtained. The row lock type to acquire is defined by `erm->markType`, which is the value previously returned by `GetForeignRowMarkType`. (`ROW_MARK_REFERENCE` means to just re-fetch the tuple without acquiring any lock, and `ROW_MARK_COPY` will never be seen by this routine.)

In addition, `*updated` should be set to `true` if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning `true` is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; returning with an empty slot is only appropriate if the `SKIP LOCKED` option is specified by `erm->waitPolicy`.

The `rowid` is the `ctid` value previously read for the row to be re-fetched. Although the `rowid` value is passed as a `Datum`, it can currently only be a `tid`. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the `RefetchForeignRow` pointer is set to `NULL`, attempts to re-fetch rows will fail with an error message.

See Section 58.5 for more information.

```
bool  
RecheckForeignScan(ForeignScanState *node,
```

```
TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to NULL and instead set `fdw_recheck_qual`s appropriately. When outer joins are pushed down, however, it isn't sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to NULL, rather than in no tuple being returned. `RecheckForeignScan` can recheck qualifiers and return true if they are still satisfied and false otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the `ForeignScan`. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops. The function `GetExistingLocalJoinPath` may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. `GetExistingLocalJoinPath` searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns NULL, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

## 58.2.7. FDW Routines for EXPLAIN

```
void  
ExplainForeignScan(ForeignScanState *node,  
                   ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call `ExplainPropertyText` and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the `ExplainForeignScan` pointer is set to NULL, no additional information is printed during EXPLAIN.

```
void  
ExplainForeignModify(ModifyTableState *mtstate,  
                    ResultRelInfo *rinfo,  
                    List *fdw_private,  
                    int subplan_index,  
                    struct ExplainState *es);
```

Print additional EXPLAIN output for a foreign table update. This function can call `ExplainPropertyText` and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the `ModifyTableState` node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for `BeginForeignModify`.

If the `ExplainForeignModify` pointer is set to NULL, no additional information is printed during EXPLAIN.

```
void  
ExplainDirectModify(ForeignScanState *node,  
                   ExplainState *es);
```

Print additional EXPLAIN output for a direct modification on the remote server. This function can call `ExplainPropertyText` and related functions to add fields to the EXPLAIN output. The flag

fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainDirectModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

## 58.2.8. FDW Routines for ANALYZE

```
bool
AnalyzeForeignTable(Relation relation,
                    AcquireSampleRowsFunc *func,
                    BlockNumber *totalpages);
```

This function is called when `ANALYZE` is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return `true`, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return `false`.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to `NULL`.

If provided, the sample collection function must have the signature

```
int
AcquireSampleRowsFunc(Relation relation,
                      int elevel,
                      HeapTuple *rows,
                      int targrows,
                      double *totalrows,
                      double *totaldeadrows);
```

A random sample of up to `targrows` rows should be collected from the table and stored into the caller-provided `rows` array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`. (Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

## 58.2.9. FDW Routines for IMPORT FOREIGN SCHEMA

```
List *
ImportForeignSchema(ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing `IMPORT FOREIGN SCHEMA`, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a `CREATE FOREIGN TABLE` command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORT_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORT_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORT_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the `NOT NULL` attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed `CREATE FOREIGN TABLE` commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it's often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

## 58.2.10. FDW Routines for Parallel Execution

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and must return each row exactly once across all cooperating processes. To do this, processes can coordinate through fixed-size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so it must not contain pointers. The following functions are all optional, but most are required if parallel execution is to be supported.

```
bool
IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel,
                          RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return true if it is safe for that scan to run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker's connection to the data can somehow be made to share the same transaction context as the leader.

If this function is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning true does not mean that the scan itself can be done in parallel, only that the scan can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

```
Size
EstimatedDSMForeignScan(ForeignScanState *node, ParallelContext
                          *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This function is optional, and can be omitted if not needed; but if it is omitted, the next three functions must be omitted as well, because no shared memory will be allocated for the FDW's use.

```
void
InitializedDSMForeignScan(ForeignScanState *node, ParallelContext
                          *pcxt,
                          void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimatedDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void
```

```
ReInitializedDSMForeignScan(ForeignScanState *node, ParallelContext
    *pcxt,
                            void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the foreign-scan plan node is about to be re-scanned. This function is optional, and can be omitted if not needed. Recommended practice is that this function reset only shared state, while the `ReScanForeignScan` function resets only local state. Currently, this function will be called before `ReScanForeignScan`, but it's best not to rely on that ordering.

```
void
InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc,
    void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `ReInitializedDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void
ShutdownForeignScan(ForeignScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndForeignScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, foreign data wrappers that wish to take some action before the DSM segment goes away should implement this method.

## 58.2.11. FDW Routines for Asynchronous Execution

A `ForeignScan` node can, optionally, support asynchronous execution as described in `src/backend/executor/README`. The following functions are all optional, but are all required if asynchronous execution is to be supported.

```
bool
IsForeignPathAsyncCapable(ForeignPath *path);
```

Test whether a given `ForeignPath` path can scan the underlying foreign relation asynchronously. This function will only be called at the end of query planning when the given path is a direct child of an `AppendPath` path and when the planner believes that asynchronous execution improves performance, and should return true if the given path is able to scan the foreign relation asynchronously.

If this function is not defined, it is assumed that the given path scans the foreign relation using `IterateForeignScan`. (This implies that the callback functions described below will never be called, so they need not be provided either.)

```
void
ForeignAsyncRequest(AsyncRequest *areq);
```

Produce one tuple asynchronously from the `ForeignScan` node. `areq` is the `AsyncRequest` struct describing the `ForeignScan` node and the parent `Append` node that requested the tuple from it. This function should store the tuple into the slot specified by `areq->result`, and set `areq->request_complete` to true; or if it needs to wait on an event external to the core server such as network I/O, and cannot produce any tuple immediately, set the flag to false, and set `areq->callback_pending` to true for the `ForeignScan` node to get a callback from the callback functions described below. If no more tuples are available, set the slot to NULL or an empty slot, and the `areq->request_complete` flag to true. It's recommended to use `ExecAsyncRequestDone` or `ExecAsyncRequestPending` to set the output parameters in the `areq`.

```
void  
ForeignAsyncConfigureWait(AsyncRequest *areq);
```

Configure a file descriptor event for which the `ForeignScan` node wishes to wait. This function will only be called when the `ForeignScan` node has the `areq->callback_pending` flag set, and should add the event to the `as_eventset` of the parent `Append` node described by the `areq`. See the comments for `ExecAsyncConfigureWait` in `src/backend/executor/execAsync.c` for additional information. When the file descriptor event occurs, `ForeignAsyncNotify` will be called.

```
void  
ForeignAsyncNotify(AsyncRequest *areq);
```

Process a relevant event that has occurred, then produce one tuple asynchronously from the `ForeignScan` node. This function should set the output parameters in the `areq` in the same way as `ForeignAsyncRequest`.

## 58.2.12. FDW Routines for Reparameterization of Paths

```
List *  
ReparameterizeForeignPathByChild(PlannerInfo *root, List  
    *fdw_private,  
                                RelOptInfo *child_rel);
```

This function is called while converting a path parameterized by the top-most parent of the given child relation `child_rel` to be parameterized by the child relation. The function is used to reparameterize any paths or translate any expression nodes saved in the given `fdw_private` member of a `ForeignPath`. The callback may use `reparameterize_path_by_child`, `adjust_appendrel_attrs` or `adjust_appendrel_attrs_multilevel` as required.

## 58.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

```
ForeignDataWrapper *  
GetForeignDataWrapperExtended(Oid fdwid, bits16 flags);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details). `flags` is a bitwise-or'd bit mask indicating an extra set of options. It can take the value `FDW_MISSING_OK`, in which case a `NULL` result is returned to the caller instead of an error for an undefined object.

```
ForeignDataWrapper *  
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).

```
ForeignServer *  
GetForeignServerExtended(Oid serverid, bits16 flags);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details). `flags` is a bitwise-or'd bit mask indicating an extra set of options. It can take the value `FSV_MISSING_OK`, in which case a `NULL` result is returned to the caller instead of an error for an undefined object.

```
ForeignServer *  
GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details).

```
UserMapping *  
GetUserMapping(Oid userid, Oid serverid);
```

This function returns a `UserMapping` object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for `PUBLIC`, or throw error if there is none.) A `UserMapping` object contains properties of the user mapping (see `foreign/foreign.h` for details).

```
ForeignTable *  
GetForeignTable(Oid relid);
```

This function returns a `ForeignTable` object for the foreign table with the given OID. A `ForeignTable` object contains properties of the foreign table (see `foreign/foreign.h` for details).

```
List *  
GetForeignColumnOptions(Oid relid, AttrNumber attnum);
```

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of `DefElem`. `NIL` is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

```
ForeignDataWrapper *  
GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return `NULL` if `missing_ok` is true, otherwise raise an error.

```
ForeignServer *  
GetForeignServerByName(const char *name, bool missing_ok);
```

This function returns a `ForeignServer` object for the foreign server with the given name. If the server is not found, return `NULL` if `missing_ok` is true, otherwise raise an error.

## 58.4. Foreign Data Wrapper Query Planning

The FDW callback functions `GetForeignRelSize`, `GetForeignPaths`, `GetForeignPlan`, `PlanForeignModify`, `GetForeignJoinPaths`, `GetForeignUpperPaths`, and

`PlanDirectModify` must fit into the workings of the PostgreSQL planner. Here are some notes about what they must do.

The information in `root` and `basere1` can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). `basere1->baserestrictinfo` is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) `basere1->reltarget->exprs` can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the `ForeignScan` plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be `palloc'd`, so that it will be reclaimed at the end of planning.

`basere1->fdw_private` is a `void` pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to `NULL` when the `RelOptInfo` node is created. It is useful for passing information forward from `GetForeignRelSize` to `GetForeignPaths` and/or `GetForeignPaths` to `GetForeignPlan`, thereby avoiding recalculation.

`GetForeignPaths` can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a `List` pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that's dumpable by `nodeToString`, for use with debugging support available in the backend.

`GetForeignPlan` can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not `NIL`, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In `GetForeignPlan`, generally the passed-in target list can be copied into the plan node as-is. The passed `scan_clauses` list contains the same clauses as `basere1->baserestrictinfo`, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip `RestrictInfo` nodes from the `scan_clauses` list (using `extract_actual_clauses`) and put all the clauses into the plan node's qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node's qual list so that the executor doesn't waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form *foreign\_variable = sub\_expression*, which it determines can be executed on the remote server given the locally-evaluated value of the *sub\_expression*. The actual identification of such a clause should happen during `GetForeignPaths`, since it would affect the cost estimate for the path. The path's `fdw_private` field would probably include a pointer to the identified clause's `RestrictInfo` node. Then `GetForeignPlan` would remove that clause from `scan_clauses`, but add the *sub\_expression* to `fdw_exprs` to ensure that it gets massaged into executable form. It would probably also put control information into the plan node's `fdw_private` field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like *WHERE foreign\_variable = \$1*, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node's qual list must instead be added to `fdw_recheck_quals` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the `READ COMMITTED` isolation level. When a concurrent update occurs for some other table involved in the query,

the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheck_quals` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to NULL without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to `NIL`, implying that the returned tuples have the row type declared for the foreign table. A non-`NIL` value must be a target list (list of `TargetEntry`s) containing Vars and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won't be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by `GetForeignJoinPaths`) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table's restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example *foreign\_variable = local\_variable*. Such clauses will not be found in `baserel->baserestrictinfo` but must be sought in the relation's join lists. A path using such a clause is called a "parameterized path". It must identify the other relations used in the selected join clause(s) with a suitable value of `param_info`; use `get_baserel_parampathinfo` to compute that value. In `GetForeignPlan`, the *local\_variable* portion of the join clause would be added to `fdw_exprs`, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, `GetForeignJoinPaths` should produce `ForeignPaths` for potential remote joins in much the same way as `GetForeignPaths` works for base tables. Information about the intended join can be passed forward to `GetForeignPlan` in the same ways described above. However, `baserestrictinfo` is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to `GetForeignJoinPaths` as a separate parameter (`extra->restrictlist`).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate *upper relation*. For example, a path representing remote aggregation should be inserted into the `UPPERREL_GROUP_AGG` relation, using `add_path`. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling `GetForeignPlan`. The recommended place to generate such paths is in the `GetForeignUpperPaths` callback function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

`PlanForeignModify` and the other callbacks described in Section 58.2.4 are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local `ModifyTable` plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the `UPPERREL_FINAL` upper relation, where it would compete against the `ModifyTable` approach. This approach could also be used to implement remote `SELECT FOR UPDATE`, rather than using the row locking callbacks described in Section 58.2.6. Keep in mind that a path inserted into `UPPERREL_FINAL` is responsible for implementing *all* behavior of the query.

When planning an `UPDATE` or `DELETE`, `PlanForeignModify` and `PlanDirectModify` can look up the `RelOptInfo` struct for the foreign table and make use of the `baserel->fdw_private` data previously created by the scan-planning functions. However, in `INSERT` the target table is not scanned so there is no `RelOptInfo` for it. The `List` returned by `PlanForeignModify` has the same restrictions as the `fdw_private` list of a `ForeignScan` plan node, that is it must contain only structures that `copyObject` knows how to copy.

INSERT with an ON CONFLICT clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that ON CONFLICT DO UPDATE is not supported, since the specification is mandatory there.

## 58.5. Row Locking in Foreign Data Wrappers

If an FDW's underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary PostgreSQL tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform *early locking* or *late locking*. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as PostgreSQL TIDs do.

By default, PostgreSQL ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in Section 58.2.6, which were added in PostgreSQL 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in READ COMMITTED isolation mode, PostgreSQL may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard PostgreSQL tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an UPDATE or DELETE on a foreign table, it is recommended that the ForeignScan operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of SELECT FOR UPDATE. An FDW can detect whether a table is an UPDATE/DELETE target at plan time by comparing its relid to root->parse->resultRelation, or at execution time by using ExecRelationIsTargetRelation(). An alternative possibility is to perform late locking within the ExecForeignUpdate or ExecForeignDelete callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a SELECT FOR UPDATE/SHARE command, the ForeignScan operation can again perform early locking by fetching tuples with the equivalent of SELECT FOR UPDATE/SHARE. To perform late locking instead, provide the callback functions defined in Section 58.2.6. In GetForeignRowMarkType, select rowmark option ROW\_MARK\_EXCLUSIVE, ROW\_MARK\_NOKEYEXCLUSIVE, ROW\_MARK\_SHARE, or ROW\_MARK\_KEYSHARE depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using get\_plan\_rowmark at plan time, or ExecFindRowMark at execution time; you must check not only whether a non-null rowmark struct is returned, but that its strength field is not LCS\_NONE.

Lastly, for foreign tables that are used in an UPDATE, DELETE or SELECT FOR UPDATE/SHARE command but are not specified to be row-locked, you can override the default choice to copy entire rows by having GetForeignRowMarkType select option ROW\_MARK\_REFERENCE when it

sees lock strength `LCS_NONE`. This will cause `RefetchForeignRow` to be called with that value for `markType`; it should then re-fetch the row without acquiring any new lock. (If you have a `GetForeignRowMarkType` function but don't wish to re-fetch unlocked rows, select option `ROW_MARK_COPY` for `LCS_NONE`.)

See `src/include/nodes/lockoptions.h`, the comments for `RowMarkType` and `Plan-RowMark` in `src/include/nodes/plannodes.h`, and the comments for `ExecRowMark` in `src/include/nodes/execnodes.h` for additional information.

---

# Chapter 59. Writing a Table Sampling Method

PostgreSQL's implementation of the `TABLESAMPLE` clause supports custom table sampling methods, in addition to the `BERNOULLI` and `SYSTEM` methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the `TABLESAMPLE` clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the `TABLESAMPLE` clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from an SQL command. The result of the function must be a palloc'd struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 59.1.

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

**List** `*parameterTypes`

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the `TABLESAMPLE` clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

**bool** `repeatable_across_queries`

If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

**bool** `repeatable_across_scans`

If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The `TsmRoutine` struct type is declared in `src/include/access/tsmapi.h`, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `src/backend/access/tablesample` subdirectory of the source tree for the built-in sampling methods, and into the `contrib` subdirectory for add-on methods.

## 59.1. Sampling Method Support Functions

The TSM handler function returns a palloc'd `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be `NULL`.

```
void
SampleScanGetSampleSize (PlannerInfo *root,
                          RelOptInfo *baserel,
                          List *paramexprs,
                          BlockNumber *pages,
                          double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the `baserel->pages` and `baserel->tuples` numbers by that, being sure to round the results to integral values.) The `paramexprs` list holds the expression(s) that are parameters to the `TABLESAMPLE` clause. It is recommended to use `estimate_expression_value()` to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they're only estimates of what the run-time values will be). The `pages` and `tuples` parameters are outputs.

```
void
InitSampleScan (SampleScanState *node,
                int eflags);
```

Initialize for execution of a `SampleScan` plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The `SampleScanState` node has already been created, but its `tsm_state` field is `NULL`. The `InitSampleScan` function can `malloc` whatever internal state data is needed by the sampling method, and store a pointer to it in `node->tsm_state`. Information about the table to scan is accessible through other fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). `eflags` contains flag bits describing the executor's operating mode for this plan node.

When `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for `EXPLAIN` and `EndSampleScan`.

This function can be omitted (set the pointer to `NULL`), in which case `BeginSampleScan` must perform all initialization needed by the sampling method.

```
void
BeginSampleScan (SampleScanState *node,
                 Datum *params,
                 int nparams,
                 uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). The `params` array, of length `nparams`, contains the values of the parameters supplied in the `TABLESAMPLE` clause. These will have the number and types specified in the sampling method's `parameterTypes` list, and have been checked to not be null. `seed` contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the `REPEATABLE` value if one was given, or the result of `random()` if not.

This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to `false` if the scan will visit only a small fraction of the table's pages. If `node->use_pagemode` is true, which it is by

default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to `false` if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don't change).

**BlockNumber**

```
NextSampleBlock (SampleScanState *node, BlockNumber nblocks);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to `NULL`), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

**OffsetNumber**

```
NextSampleTuple (SampleScanState *node,  
                 BlockNumber blockno,  
                 OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

### Note

`NextSampleTuple` is not explicitly told which of the offset numbers in the range `1 .. maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can use `node->donetuples` to examine how many of the tuples it returned were valid and visible.

### Note

`NextSampleTuple` must *not* assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

**void**

```
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release palloc'd memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to `NULL`) in the common case where no such resources exist.

---

# Chapter 60. Writing a Custom Scan Provider

PostgreSQL supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a foreign data wrapper, which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

## 60.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather and Gather Merge paths, which are made after this call so that they can use partial paths added by the hook):

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                           RelOptInfo *rel,
                                           Index rti,
                                           RangeTblEntry *rte);

extern PGDLLIMPORT set_rel_pathlist_hook_type
set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`, or `add_partial_path` if they are partial paths. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List      *custom_paths;
    List      *custom_restrictinfo;
    List      *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which specifies whether the scan provider can support certain optional capabilities. `flags` should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan, `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore, and `CUSTOMPATH_SUPPORT_PROJECTION` if it can perform projections. (If `CUSTOMPATH_SUPPORT_PROJECTION` is not set, the scan node will only be asked to produce Vars of the scanned relation; while if that flag is set, the scan node must be able to evaluate scalar expressions over these Vars.) An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by

planner. As described below, custom paths can be created for join relations as well. In such a case, `custom_restrictinfo` should be used to store the set of join clauses to apply to the join the custom path replaces. Otherwise it should be NIL. `custom_private` can be used to store the custom path's private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, which are further detailed below.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath` path(s) for the join relation.

```
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                             RelOptInfo *joinrel,
                                             RelOptInfo *outerrel,
                                             RelOptInfo *innerrel,
                                             JoinType jointype,
                                             JoinPathExtraData
                                             *extra);
extern PGDLLIMPORT set_join_pathlist_hook_type
set_join_pathlist_hook;
```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

Note also that the set of join clauses to apply to the join, which is passed as `extra->restrictlist`, varies depending on the combination of inner and outer relations. A `CustomPath` path generated for the `joinrel` must contain the set of join clauses it uses, which will be used by the planner to convert the `CustomPath` path into a plan, if it is selected by the planner as the best path for the `joinrel`.

### 60.1.1. Custom Scan Path Callbacks

```
Plan *(*PlanCustomPath) (PlannerInfo *root,
                          RelOptInfo *rel,
                          CustomPath *best_path,
                          List *tlist,
                          List *clauses,
                          List *custom_plans);
```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See Section 60.2 for more details.

```
List *(*ReparameterizeCustomPathByChild) (PlannerInfo *root,
                                           List *custom_private,
                                           RelOptInfo *child_rel);
```

This callback is called while converting a path parameterized by the top-most parent of the given child relation `child_rel` to be parameterized by the child relation. The callback is used to reparameterize any paths or translate any expression nodes saved in the given `custom_private` member of a `CustomPath`. The callback may use `reparameterize_path_by_child`, `adjust_appendrel_attrs` or `adjust_appendrel_attrs_multilevel` as required.

## 60.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```
typedef struct CustomScan
{
    Scan      scan;
    uint32    flags;
    List      *custom_plans;
    List      *custom_exprs;
    List      *custom_private;
    List      *custom_scan_tlist;
    Bitmapset *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;
```

`scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child `Plan` nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be `NIL` when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation's row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

### 60.2.1. Custom Scan Plan Callbacks

```
Node *(*CreateCustomScanState) (CustomScan *cscan);
```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and `methods` set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

## 60.3. Executing Custom Scans

When a `CustomScan` is executed, its execution state is represented by a `CustomScanState`, which is declared as follows:

```
typedef struct CustomScanState
{
    ScanState ss;
    uint32    flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

SS is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, `ss.ss_currentRelation` is left NULL. `flags` is a bit mask with the same meaning as in `CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a `CustomScanState`, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

## 60.3.1. Custom Scan Execution Callbacks

```
void (*BeginCustomScan) (CustomScanState *node,  
                        Estate *estate,  
                        int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, NULL or an empty slot should be returned.

```
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
Size (*EstimateDSMCustomScan) (CustomScanState *node,  
                               ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializedDSMCustomScan) (CustomScanState *node,  
                                  ParallelContext *pcxt,
```

```
void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimatedDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ReInitializedDSMCustomScan) (CustomScanState *node,  
                                     ParallelContext *pcxt,  
                                     void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the custom-scan plan node is about to be re-scanned. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution. Recommended practice is that this callback reset only shared state, while the `ReScanCustomScan` callback resets only local state. Currently, this callback will be called before `ReScanCustomScan`, but it's best not to rely on that ordering.

```
void (*InitializeWorkerCustomScan) (CustomScanState *node,  
                                     shm_toc *toc,  
                                     void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializedDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ShutdownCustomScan) (CustomScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndCustomScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, custom scan providers that wish to take some action before the DSM segment goes away should implement this method.

```
void (*ExplainCustomScan) (CustomScanState *node,  
                           List *ancestors,  
                           ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.

---

# Chapter 61. Genetic Query Optimizer

## Author

Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

## 61.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

## 61.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population* of *individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors. Figure 61.1 illustrates these steps.

Figure 61.1. Structure of a Genetic Algorithm

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

### 61.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:

- Usage of a *steady state* GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley's Genitor algorithm.

The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

### 61.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

### 61.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file `src/backend/optimizer/geqo/geqo_main.c`, routines `gimme_pool_size` and `gimme_number_generations`, we have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

# Chapter 62. Table Access Method Interface Definition

This chapter explains the interface between the core PostgreSQL system and *table access methods*, which manage the storage for tables. The core system knows little about these access methods beyond what is specified here, so it is possible to develop entirely new access method types by writing add-on code.

Each table access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the table access method. These entries can be created and deleted using the `CREATE ACCESS METHOD` and `DROP ACCESS METHOD` SQL commands.

A table access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `table_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands.

Here is how an extension SQL script file might create a table access method handler:

```
CREATE OR REPLACE FUNCTION my_tableam_handler(internal)
    RETURNS table_am_handler AS 'my_extension', 'my_tableam_handler'
    LANGUAGE C STRICT;
```

```
CREATE ACCESS METHOD myam TYPE TABLE HANDLER my_tableam_handler;
```

The result of the function must be a pointer to a struct of type `TableAmRoutine`, which contains everything that the core code needs to know to make use of the table access method. The return value needs to be of server lifetime, which is typically achieved by defining it as a `static const` variable in global scope.

Here is how a source file with the table access method handler might look like:

```
#include "postgres.h"

#include "access/tableam.h"
#include "fmgr.h"

PG_MODULE_MAGIC;

static const TableAmRoutine my_tableam_methods = {
    .type = T_TableAmRoutine,

    /* Methods of TableAmRoutine omitted from example, add them
    here. */
};

PG_FUNCTION_INFO_V1(my_tableam_handler);

Datum
my_tableam_handler(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(&my_tableam_methods);
}
```

The `TableAmRoutine` struct, also called the access method's *API struct*, defines the behavior of the access method using callbacks. These callbacks are pointers to plain C functions and are not vis-

ible or callable at the SQL level. All the callbacks and their behavior is defined in the `TableAmRoutine` structure (with comments inside the struct defining the requirements for callbacks). Most callbacks have wrapper functions, which are documented from the point of view of a user (rather than an implementor) of the table access method. For details, please refer to the `src/include/access/tableam.h`<sup>1</sup> file.

To implement an access method, an implementor will typically need to implement an AM-specific type of tuple table slot (see `src/include/executor/tuptable.h`<sup>2</sup>), which allows code outside the access method to hold references to tuples of the AM, and to access the columns of the tuple.

Currently, the way an AM actually stores data is fairly unconstrained. For example, it's possible, but not required, to use postgres' shared buffer cache. In case it is used, it likely makes sense to use PostgreSQL's standard page layout as described in Section 66.6.

One fairly large constraint of the table access method API is that, currently, if the AM wants to support modifications and/or indexes, it is necessary for each tuple to have a tuple identifier (TID) consisting of a block number and an item number (see also Section 66.6). It is not strictly necessary that the sub-parts of TIDs have the same meaning they e.g., have for `heap`, but if bitmap scan support is desired (it is optional), the block number needs to provide locality.

For crash safety, an AM can use postgres' WAL, or a custom implementation. If WAL is chosen, either Generic WAL Records can be used, or a Custom WAL Resource Manager can be implemented.

To implement transactional support in a manner that allows different table access methods be accessed within a single transaction, it likely is necessary to closely integrate with the machinery in `src/backend/access/transam/xlog.c`.

Any developer of a new `table access method` can refer to the existing `heap` implementation present in `src/backend/access/heap/heapam_handler.c` for details of its implementation.

# Chapter 63. Index Access Method Interface Definition

This chapter defines the interface between the core PostgreSQL system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 66.6, and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see Section 66.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

## 63.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the index access method. These entries can be created and deleted using the `CREATE ACCESS METHOD` and `DROP ACCESS METHOD` SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method's *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 63.2.

The structure `IndexAmRoutine` is defined thus:

```
typedef struct IndexAmRoutine
{
    NodeTag      type;

    /*
     * Total number of strategies (operators) by which we can
     * traverse/search
     * this AM. Zero if AM does not have a fixed set of strategy
     * assignments.
     */
}
```

```

uint16      amstrategies;
/* total number of support functions that this AM uses */
uint16      amsupport;
/* opclass options support function number or 0 */
uint16      amoptsprocnum;
/* does AM support ORDER BY indexed column's value? */
bool        amcanorder;
/* does AM support ORDER BY result of an operator on indexed
column? */
bool        amcanorderbyop;
/* does AM support hashing using API consistent with the hash
AM? */
bool        amcanhash;
/* do operators within an opfamily have consistent equality
semantics? */
bool        amconsistentequality;
/* do operators within an opfamily have consistent ordering
semantics? */
bool        amconsistentordering;
/* does AM support backward scanning? */
bool        amcanbackward;
/* does AM support UNIQUE indexes? */
bool        amcanunique;
/* does AM support multi-column indexes? */
bool        amcanmulticol;
/* does AM require scans to have a constraint on the first
index column? */
bool        amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool        amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool        amsearchnulls;
/* can index storage data type differ from column data type? */
bool        amstorage;
/* can an index of this type be clustered on? */
bool        amclusterable;
/* does AM handle predicate locks? */
bool        ampredlocks;
/* does AM support parallel scan? */
bool        amcanparallel;
/* does AM support parallel build? */
bool        amcanbuildparallel;
/* does AM support columns included with clause INCLUDE? */
bool        amcaninclude;
/* does AM use maintenance_work_mem? */
bool        amusemaintenanceworkmem;
/* does AM summarize tuples, with at least all tuples in the
block
* summarized in one summary */
bool        amsummarizing;
/* OR of parallel vacuum flags */
uint8       amparallelvacuumoptions;
/* type of data stored in index, or InvalidOid if variable */
Oid         amkeytype;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;

```

```

    aminsert_function aminsert;
    aminsertcleanup_function aminsertcleanup;    /* can be NULL */
    ambulkdelete_function ambulkdelete;
    amvacuumcleanup_function amvacuumcleanup;
    amcanreturn_function amcanreturn;    /* can be NULL */
    amcostestimate_function amcostestimate;
    amgettreeheight_function amgettreeheight;    /* can be NULL */
    amoptions_function amoptions;

    ambuildphasename_function ambuildphasename;    /* can be NULL */
    amvalidate_function amvalidate;
    amadjustmembers_function amadjustmembers;    /* can be NULL */
    ambeginscan_function ambeginscan;
    amrescan_function amrescan;
    amgettuple_function amgettuple;    /* can be NULL */
    amgetbitmap_function amgetbitmap;    /* can be NULL */
    amendscan_function amendscan;
    ammarkpos_function ammarkpos;    /* can be NULL */
    amrestrpos_function amrestrpos;    /* can be NULL */

    /* interface functions to support parallel index scans */
    amestimateparallelscan_function amestimateparallelscan;    /*
can be NULL */
    aminitparallelscan_function aminitparallelscan;    /* can be
NULL */
    amparallelrescan_function amparallelrescan;    /* can be NULL
*/

    /* interface functions to support planning */
    amtranslate_strategy_function amtranslatestrategy;    /* can be
NULL */
    amtranslate_cmptype_function amtranslatecmptype;    /* can be
NULL */
} IndexAmRoutine;

```

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 36.16, which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in `pg_index`. Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag fields of `IndexAmRoutine` have nonobvious implications. The requirements of `amcanunique` are discussed in Section 63.5. The `amcanmulticol` flag asserts that the access method supports multi-key-column indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn't index null values.

Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

The `amcaninclude` flag indicates whether the access method supports “included” columns, that is it can store (without processing) additional columns beyond the key column(s). The requirements of the preceding paragraph apply only to the key columns. In particular, the combination of `amcanmulticol=false` and `amcaninclude=true` is sensible: it means that there can only be one key column, but there can also be included column(s). Also, included columns must be allowed to be null, independently of `amoptionalkey`.

The `amsummarizing` flag indicates whether the access method summarizes the indexed tuples, with summarizing granularity of at least per block. Access methods that do not point to individual tuples, but to block ranges (like BRIN), may allow the HOT optimization to continue. This does not apply to attributes referenced in index predicates, an update of such an attribute always disables HOT.

## 63.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in `IndexAmRoutine` are:

```
IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `table_index_build_scan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a `palloc'd` struct containing statistics about the new index. The `amcanbuildparallel` flag indicates whether the access method supports parallel index builds. When set to `true`, the system will attempt to allocate parallel workers for the build. Access methods supporting only non-parallel index builds should leave this flag set to `false`.

```
void
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (`INIT_FORKNUM`) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```
bool
aminert (Relation indexRelation,
         Datum *values,
         bool *isnull,
         ItemPointer heap_tid,
```

```

Relation heapRelation,
IndexUniqueCheck checkUnique,
bool indexUnchanged,
IndexInfo *indexInfo);

```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `amcanunique` flag is true) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 63.5 for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The `indexUnchanged` Boolean value gives a hint about the nature of the tuple to be indexed. When it is true, the tuple is a duplicate of some existing tuple in the index. The new tuple is a logically unchanged successor MVCC tuple version. This happens when an `UPDATE` takes place that does not modify any columns covered by the index, but nevertheless requires a new version in the index. The index AM may use this hint to decide to apply bottom-up index deletion in parts of the index where many versions of the same logical row accumulate. Note that updating a non-key column or a column that only appears in a partial index predicate does not affect the value of `indexUnchanged`. The core code determines each tuple's `indexUnchanged` value using a low overhead approach that allows both false positives and false negatives. Index AMs must not treat `indexUnchanged` as an authoritative source of information about tuple visibility or versioning.

The function's Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a true result means the new entry is known unique, whereas false means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant false result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `aminsert` should just return without doing anything.

If the index AM wishes to cache data across successive index insertions within an SQL statement, it can allocate space in `indexInfo->ii_Context` and store a pointer to the data in `indexInfo->ii_AmCache` (which will be NULL initially). If resources other than memory have to be released after index insertions, `aminsertcleanup` may be provided, which will be called before the memory is released.

```

void
aminsertcleanup (Relation indexRelation,
                 IndexInfo *indexInfo);

```

Clean up state that was maintained across successive inserts in `indexInfo->ii_AmCache`. This is useful if the data requires additional cleanup steps (e.g., releasing pinned buffers), and simply releasing the memory is not sufficient.

```

IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
              IndexBulkDeleteResult *stats,
              IndexBulkDeleteCallback callback,
              void *callback_state);

```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a `VACUUM` operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                 IndexBulkDeleteResult *stats);
```

Clean up after a `VACUUM` operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc'd struct. The statistics it contains will be used to update `pg_class`, and will be reported by `VACUUM` if `VERBOSE` is given. It is OK to return NULL if the index was not changed at all during the `VACUUM` operation, but otherwise correct stats should be returned.

`amvacuumcleanup` will also be called at completion of an `ANALYZE` operation. In this case `stats` is always NULL and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```
bool
amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support *index-only scans* on the given column, by returning the column's original indexed value. The attribute number is 1-based, i.e., the first column's `attno` is 1. Returns true if supported, else false. This function should always return true for included columns (if those are supported), since there's little point in an included column that can't be retrieved. If the access method does not support index-only scans at all, the `amcanreturn` field in its `IndexAmRoutine` struct can be set to NULL.

```
void
amcostestimate (PlannerInfo *root,
                IndexPath *path,
                double loop_count,
                Cost *indexStartupCost,
                Cost *indexTotalCost,
                Selectivity *indexSelectivity,
                double *indexCorrelation,
                double *indexPages);
```

Estimate the costs of an index scan. This function is described fully in Section 63.6, below.

```
int
amgettreeheight (Relation rel);
```

Compute the height of a tree-shaped index. This information is supplied to the `amcostestimate` function in `path->indexinfo->tree_height` and can be used to support the cost estimation. The result is not used anywhere else, so this function can actually be used to compute any kind of data (that fits into an integer) about the index that the cost estimation function might want to know. If the computation is expensive, it could be useful to cache the result as part of `RelationData.rd_am-cache`.

```
bytea *
amoptions (ArrayType *reloptions,
           bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. *reloptions* is a text array containing entries of the form *name=value*. The function should construct a bytea value, which will be copied into the *rd\_options* field of the index's relcache entry. The data contents of the bytea value are open for the access method to define; most of the standard access methods use struct *StdRdOptions*. When *validate* is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when *validate* is false, invalid entries should be silently ignored. (*validate* is false when loading options already stored in *pg\_catalog*; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

```
bool
amproperty (Oid index_oid, int attno,
            IndexAMProperty prop, const char *propname,
            bool *res, bool *isnull);
```

The *amproperty* method allows index access methods to override the default behavior of *pg\_index\_column\_has\_property* and related functions. If the access method does not have any special behavior for index property inquiries, the *amproperty* field in its *IndexAmRoutine* struct can be set to NULL. Otherwise, the *amproperty* method will be called with *index\_oid* and *attno* both zero for *pg\_indexam\_has\_property* calls, or with *index\_oid* valid and *attno* zero for *pg\_index\_has\_property* calls, or with *index\_oid* valid and *attno* greater than zero for *pg\_index\_column\_has\_property* calls. *prop* is an enum value identifying the property being tested, while *propname* is the original property name string. If the core code does not recognize the property name then *prop* is *AMPROP\_UNKNOWN*. Access methods can define custom property names by checking *propname* for a match (use *pg\_strcasecmp* to match, for consistency with the core code); for names known to the core code, it's better to inspect *prop*. If the *amproperty* method returns true then it has determined the property test result: it must set *\*res* to the Boolean value to return, or set *\*isnull* to true to return a NULL. (Both of the referenced variables are initialized to false before the call.) If the *amproperty* method returns false then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement *AMPROP\_DISTANCE\_ORDERABLE* property testing, as the core code does not know how to do that and will return NULL. It may also be advantageous to implement *AMPROP\_RETURNABLE* testing, if that can be done more cheaply than by opening the index and calling *amcanreturn*, which is the core code's default behavior. The default behavior should be satisfactory for all other standard properties.

```
char *
ambuildphasename (int64 phasenum);
```

Return the textual name of the given build phase number. The phase numbers are those reported during an index build via the *pgstat\_progress\_update\_param* interface. The phase names are then exposed in the *pg\_stat\_progress\_create\_index* view.

```
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The *amvalidate* function must return false if the opclass is invalid. Problems should be reported with *ereport* messages, typically at INFO level.

```
void
amadjustmembers (Oid opfamilyoid,
                 Oid opclassoid,
                 List *operators,
                 List *functions);
```

Validate proposed new operator and function members of an operator family, so far as the access method can reasonably do that, and set their dependency types if the default is not satisfactory. This is called during `CREATE OPERATOR CLASS` and during `ALTER OPERATOR FAMILY ADD`; in the latter case *opclassoid* is `InvalidOid`. The `List` arguments are lists of `OpFamilyMember` structs, as defined in `amapi.h`. Tests done by this function will typically be a subset of those performed by `amvalidate`, since `amadjustmembers` cannot assume that it is seeing a complete set of members. For example, it would be reasonable to check the signature of a support function, but not to check whether all required support functions are provided. Any problems can be reported by throwing an error. The dependency-related fields of the `OpFamilyMember` structs are initialized by the core code to create hard dependencies on the `opclass` if this is `CREATE OPERATOR CLASS`, or soft dependencies on the `opfamily` if this is `ALTER OPERATOR FAMILY ADD`. `amadjustmembers` can adjust these fields if some other behavior is more appropriate. For example, GIN, GiST, and SP-GiST always set operator members to have soft dependencies on the `opfamily`, since the connection between an operator and an `opclass` is relatively weak in these index types; so it is reasonable to allow operator members to be added and removed freely. Optional support functions are typically also given soft dependencies, so that they can be removed if necessary.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in Section 63.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
             int nkeys,
             int norderbys);
```

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```
void
amrescan (IndexScanDesc scan,
          ScanKey keys,
          int nkeys,
          ScanKey orderbys,
          int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, `NULL` is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```
bool
amgettupple (IndexScanDesc scan,
```

`ScanDirection direction);`

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns true if a tuple was obtained, false if no matching tuples remain. In the true case the tuple TID is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettuple` must also set `scan->xs_recheck` to true or false. False means it is certain that the index entry matches the scan keys. True means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettuple` callers.

If the index supports index-only scans (i.e., `amcanreturn` returns true for any of its columns), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the originally indexed data for the index entry. Columns for which `amcanreturn` returns false can be returned as nulls. The data can be returned in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`; or in the form of a `HeapTuple` pointer stored at `scan->xs_hitup`, with tuple descriptor `scan->xs_hitupdesc`. (The latter format should be used when reconstructing data that might possibly not fit into an `IndexTuple`.) In either case, management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettuple`, `amrescan`, or `amendscan` call for the scan.

The `amgettuple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettuple` field in its `IndexAmRoutine` struct must be set to NULL.

```
int64
amgetbitmap (IndexScanDesc scan,
             TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied `TIDBitmap` (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettuple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettuple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in Section 63.3.

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the `amgetbitmap` field in its `IndexAmRoutine` struct must be set to NULL.

```
void
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by `ambeginscan` and other scan-related functions.

```
void
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to NULL.

```
void  
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

In addition to supporting ordinary index scans, some types of index may wish to support *parallel index scans*, which allow multiple backends to cooperate in performing an index scan. The index access method should arrange things so that each cooperating process returns a subset of the tuples that would be performed by an ordinary, non-parallel index scan, but in such a way that the union of those subsets is equal to the set of tuples that would be returned by an ordinary, non-parallel index scan. Furthermore, while there need not be any global ordering of tuples returned by a parallel scan, the ordering of that subset of tuples returned within each cooperating backend must match the requested ordering. The following functions may be implemented to support parallel index scans:

```
Size  
amestimateparallelscale (Relation indexRelation,  
                          int nkeys,  
                          int norderbys);
```

Estimate and return the number of bytes of dynamic shared memory which the access method will be needed to perform a parallel scan. (This number is in addition to, not in lieu of, the amount of space needed for AM-independent data in `ParallelIndexScanDescData`.)

The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; the same values will be passed to `amrescan`. Note that the actual values of the scan keys aren't provided yet.

It is not necessary to implement this function for access methods which do not support parallel scans or for which the number of additional bytes of storage required is zero.

```
void  
aminitparallelscale (void *target);
```

This function will be called to initialize dynamic shared memory at the beginning of a parallel scan. *target* will point to at least the number of bytes previously returned by `amestimateparallelscale`, and this function may use that amount of space to store whatever data it wishes.

It is not necessary to implement this function for access methods which do not support parallel scans or in cases where the shared memory space required needs no initialization.

```
void  
amparallelrescale (IndexScanDesc scan);
```

This function, if implemented, will be called when a parallel index scan must be restarted. It should reset any shared state set up by `aminitparallelscale` such that the scan will be restarted from the beginning.

```
CompareType  
amtranslatestrategy (StrategyNumber strategy, Oid opfamily, Oid  
                   opcintype);
```

StrategyNumber

```
amtranslatecmptype (CompareType cmptype, Oid opfamily, Oid
opcintype);
```

These functions, if implemented, will be called by the planner and executor to convert between fixed `CompareType` values and the specific strategy numbers used by the access method. These functions can be implemented by access methods that implement functionality similar to the built-in btree or hash access methods, and by implementing these translations, the system can learn about the semantics of the access method's operations and can use them in place of btree or hash indexes in various places. If the functionality of the access method is not similar to those built-in access methods, these functions do not need to be implemented. If the functions are not implemented, the access method will be ignored for certain planner and executor decisions, but is otherwise fully functional.

## 63.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's visibility test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index\_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettup` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettup` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettup` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestrpos` functions in `IndexAmRoutine`; set those pointers to `NULL` instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method's.

Instead of using `amgettupple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettupple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettupple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 63.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettupple`, or vice versa, if its internal implementation is unsuited to one API or the other.

## 63.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An `ACCESS EXCLUSIVE` lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX (SHARE UPDATE EXCLUSIVE)` is taken instead with `CONCURRENTLY`.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in `src/backend/access/nbtree/README` and `src/backend/access/hash/README`.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 63.5.)
- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.

- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already reused the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

## 63.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns listed in the `INCLUDE` clause are not considered when enforcing uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an `UPDATE` always deletes the old row version before inserting the new version, this will allow an `UPDATE` on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry's HOT chain is live”.) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row's index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning false from `aminsert`. For each row for which false is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must *not* insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

## 63.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of `WHERE` and `ORDER BY` clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the `WHERE` clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point

of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void  
amcostestimate (PlannerInfo *root,  
                IndexPath *path,  
                double loop_count,  
                Cost *indexStartupCost,  
                Cost *indexTotalCost,  
                Selectivity *indexSelectivity,  
                double *indexCorrelation,  
                double *indexPages);
```

The first three parameters are inputs:

*root*

The planner's information about the query being processed.

*path*

The index access path being considered. All fields except cost and selectivity values are valid.

*loop\_count*

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger *loop\_count* means that it may be appropriate to allow for some caching effects across multiple scans.

The last five parameters are pass-by-reference outputs:

*\*indexStartupCost*

Set to cost of index start-up processing

*\*indexTotalCost*

Set to total cost of index processing

*\*indexSelectivity*

Set to index selectivity

*\*indexCorrelation*

Set to correlation coefficient between index scan order and underlying table's order

*\*indexPages*

Set to number of index leaf pages

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operat`

`tor_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the `indexquals` themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but *not* the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The *indexSelectivity* should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The *indexCorrelation* should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

The *indexPages* should be set to the number of leaf pages. This is used to estimate the number of workers for parallel index scan.

When *loop\_count* is greater than one, the returned numbers should be averages expected for any one scan of the index.

## Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:

```
*indexSelectivity = clauselist_selectivity(root, path->indexquals,
                                           path->indexinfo->rel->reloid,
                                           JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as *indexSelectivity* times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just *indexSelectivity* times the index's size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not
 * random_page_cost.
 * Also, we charge for evaluation of the indexquals at each
 * index row.
 * All the costs are assumed to be paid incrementally during
 * the scan.
 */
cost_qual_eval(&index_qual_cost, path->indexquals, root);
```

```
*indexStartupCost = index_qual_cost.startup;  
*indexTotalCost = seq_page_cost * numIndexPages +  
    (cpu_index_tuple_cost + index_qual_cost.per_tuple) *  
    numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`.

---

# Chapter 64. Write Ahead Logging for Extensions

Certain extensions, principally extensions that implement custom access methods, may need to perform write-ahead logging in order to ensure crash-safety. PostgreSQL provides two ways for extensions to achieve this goal.

First, extensions can choose to use generic WAL, a special type of WAL record which describes changes to pages in a generic way. This method is simple to implement and does not require that an extension library be loaded in order to apply the records. However, generic WAL records will be ignored when performing logical decoding.

Second, extensions can choose to use a custom resource manager. This method is more flexible, supports logical decoding, and can sometimes generate much smaller write-ahead log records than would be possible with generic WAL. However, it is more complex for an extension to implement.

## 64.1. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way.

### Note

Generic WAL records are ignored during Logical Decoding. If logical decoding is required for your extension, consider a Custom WAL Resource Manager.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's

responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.

- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.
- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.
- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.
- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.
- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.
- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.

## 64.2. Custom WAL Resource Managers

This section explains the interface between the core PostgreSQL system and custom WAL resource managers, which enable extensions to integrate directly with the WAL.

An extension, especially a Table Access Method or Index Access Method, may need to use WAL for recovery, replication, and/or Logical Decoding.

To create a new custom WAL resource manager, first define an `RmgrData` structure with implementations for the resource manager methods. Refer to `src/backend/access/transam/README` and `src/include/access/xlog_internal.h` in the PostgreSQL source.

```
/*
 * Method table for resource managers.
 *
 * This struct must be kept in sync with the PG_RMGR definition in
 * rmgr.c.
 *
 * rm_identify must return a name for the record based on xl_info
 * (without
 * reference to the rmid). For example, XLOG_BTREE_VACUUM would be
 * named
 * "VACUUM". rm_desc can then be called to obtain additional detail
 * for the
 * record, if available (e.g. the last block).
```

```
*
* rm_mask takes as input a page modified by the resource manager
* and masks
* out bits that shouldn't be flagged by wal_consistency_checking.
*
* RmgrTable[] is indexed by RmgrId values (see rmgrlist.h). If
* rm_name is
* NULL, the corresponding RmgrTable entry is considered invalid.
*/
typedef struct RmgrData
{
    const char *rm_name;
    void        (*rm_redo) (XLogReaderState *record);
    void        (*rm_desc) (StringInfo buf, XLogReaderState
*record);
    const char *(*rm_identify) (uint8 info);
    void        (*rm_startup) (void);
    void        (*rm_cleanup) (void);
    void        (*rm_mask) (char *pagedata, BlockNumber blkno);
    void        (*rm_decode) (struct LogicalDecodingContext *ctx,
                             struct XLogRecordBuffer *buf);
} RmgrData;
```

The `src/test/modules/test_custom_rmgrs` module contains a working example, which demonstrates usage of custom WAL resource managers.

Then, register your new resource manager.

```
/*
* Register a new custom WAL resource manager.
*
* Resource manager IDs must be globally unique across all
* extensions. Refer
* to https://wiki.postgresql.org/wiki/CustomWALResourceManagers to
* reserve a
* unique RmgrId for your extension, to avoid conflicts with other
* extension
* developers. During development, use RM_EXPERIMENTAL_ID to avoid
* needlessly
* reserving a new ID.
*/
extern void RegisterCustomRmgr(RmgrId rmid, const RmgrData *rmgr);
```

`RegisterCustomRmgr` must be called from the extension module's `_PG_init` function. While developing a new extension, use `RM_EXPERIMENTAL_ID` for *rmid*. When you are ready to release the extension to users, reserve a new resource manager ID at the Custom WAL Resource Manager<sup>1</sup> page.

Place the extension module implementing the custom resource manager in `shared_preload_libraries` so that it will be loaded early during PostgreSQL startup.

### Note

The extension must remain in `shared_preload_libraries` as long as any custom WAL records may exist in the system. Otherwise PostgreSQL will not be able to apply or decode the custom WAL records, which may prevent the server from starting.

# Chapter 65. Built-in Index Access Methods

## 65.1. B-Tree Indexes

### 65.1.1. Introduction

PostgreSQL includes an implementation of the standard btree (multi-way balanced tree) index data structure. Any data type that can be sorted into a well-defined linear order can be indexed by a btree index. The only limitation is that an index entry cannot exceed approximately one-third of a page (after TOAST compression, if applicable).

Because each btree operator class imposes a sort order on its data type, btree operator classes (or, really, operator families) have come to be used as PostgreSQL's general representation and understanding of sorting semantics. Therefore, they've acquired some features that go beyond what would be needed just to support btree indexes, and parts of the system that are quite distant from the btree AM make use of them.

### 65.1.2. Behavior of B-Tree Operator Classes

As shown in Table 36.3, a btree operator class must provide five comparison operators,  $<$ ,  $<=$ ,  $=$ ,  $>=$  and  $>$ . One might expect that  $<>$  should also be part of the operator class, but it is not, because it would almost never be useful to use a  $<>$  WHERE clause in an index search. (For some purposes, the planner treats  $<>$  as associated with a btree operator class; but it finds that operator via the  $=$  operator's negator link, rather than from `pg_amop`.)

When several data types share near-identical sorting semantics, their operator classes can be grouped into an operator family. Doing so is advantageous because it allows the planner to make deductions about cross-type comparisons. Each operator class within the family should contain the single-type operators (and associated support functions) for its input data type, while cross-type comparison operators and support functions are “loose” in the family. It is recommendable that a complete set of cross-type operators be included in the family, thus ensuring that the planner can represent any comparison conditions that it deduces from transitivity.

There are some basic assumptions that a btree operator family must satisfy:

- An  $=$  operator must be an equivalence relation; that is, for all non-null values  $A, B, C$  of the data type:
  - $A = A$  is true (*reflexive law*)
  - if  $A = B$ , then  $B = A$  (*symmetric law*)
  - if  $A = B$  and  $B = C$ , then  $A = C$  (*transitive law*)
- A  $<$  operator must be a strong ordering relation; that is, for all non-null values  $A, B, C$ :
  - $A < A$  is false (*irreflexive law*)
  - if  $A < B$  and  $B < C$ , then  $A < C$  (*transitive law*)
- Furthermore, the ordering is total; that is, for all non-null values  $A, B$ :
  - exactly one of  $A < B$ ,  $A = B$ , and  $B < A$  is true (*trichotomy law*)(The trichotomy law justifies the definition of the comparison support function, of course.)

The other three operators are defined in terms of  $=$  and  $<$  in the obvious way, and must act consistently with them.

For an operator family supporting multiple data types, the above laws must hold when *A*, *B*, *C* are taken from any data types in the family. The transitive laws are the trickiest to ensure, as in cross-type situations they represent statements that the behaviors of two or three different operators are consistent. As an example, it would not work to put `float8` and `numeric` into the same operator family, at least not with the current semantics that `numeric` values are converted to `float8` for comparison to a `float8`. Because of the limited accuracy of `float8`, this means there are distinct `numeric` values that will compare equal to the same `float8` value, and thus the transitive law would fail.

Another requirement for a multiple-data-type family is that any implicit or binary-coercion casts that are defined between data types included in the operator family must not change the associated sort ordering.

It should be fairly clear why a btree index requires these laws to hold within a single data type: without them there is no ordering to arrange the keys with. Also, index searches using a comparison key of a different data type require comparisons to behave sanely across two data types. The extensions to three or more data types within a family are not strictly required by the btree index mechanism itself, but the planner relies on them for optimization purposes.

### 65.1.3. B-Tree Support Functions

As shown in Table 36.9, btree defines one required and five optional support functions. The six user-defined methods are:

#### order

For each combination of data types that a btree operator family provides comparison operators for, it must provide a comparison support function, registered in `pg_amproc` with support function number 1 and `amproclefttype/amprocrighttype` equal to the left and right data types for the comparison (i.e., the same data types that the matching operators are registered with in `pg_amop`). The comparison function must take two non-null values *A* and *B* and return an `int32` value that is `< 0`, `0`, or `> 0` when  $A < B$ ,  $A = B$ , or  $A > B$ , respectively. A null result is disallowed: all values of the data type must be comparable. See `src/backend/access/nbtree/nbt-compare.c` for examples.

If the compared values are of a collatable data type, the appropriate collation OID will be passed to the comparison support function, using the standard `PG_GET_COLLATION()` mechanism.

#### sortsupport

Optionally, a btree operator family may provide *sort support* function(s), registered under support function number 2. These functions allow implementing comparisons for sorting purposes in a more efficient way than naively calling the comparison support function. The APIs involved in this are defined in `src/include/utils/sortsupport.h`.

#### in\_range

Optionally, a btree operator family may provide *in\_range* support function(s), registered under support function number 3. These are not used during btree index operations; rather, they extend the semantics of the operator family so that it can support window clauses containing the `RANGE offset PRECEDING` and `RANGE offset FOLLOWING` frame bound types (see Section 4.2.8). Fundamentally, the extra information provided is how to add or subtract an *offset* value in a way that is compatible with the family's data ordering.

An *in\_range* function must have the signature

```
in_range(val type1, base type1, offset type2, sub bool, less
        bool)
returns bool
```

*val* and *base* must be of the same type, which is one of the types supported by the operator family (i.e., a type for which it provides an ordering). However, *offset* could be of a different

type, which might be one otherwise unsupported by the family. An example is that the built-in `time_ops` family provides an `in_range` function that has *offset* of type `interval`. A family can provide `in_range` functions for any of its supported types and one or more *offset* types. Each `in_range` function should be entered in `pg_amproc` with `amproclefttype` equal to `type1` and `amprocrighttype` equal to `type2`.

The essential semantics of an `in_range` function depend on the two Boolean flag parameters. It should add or subtract *base* and *offset*, then compare *val* to the result, as follows:

- if *!sub* and *!less*, return  $val \geq (base + offset)$
- if *!sub* and *less*, return  $val \leq (base + offset)$
- if *sub* and *!less*, return  $val \geq (base - offset)$
- if *sub* and *less*, return  $val \leq (base - offset)$

Before doing so, the function should check the sign of *offset*: if it is less than zero, raise error `ERRCODE_INVALID_PRECEDING_OR_FOLLOWING_SIZE` (22013) with error text like “invalid preceding or following size in window function”. (This is required by the SQL standard, although nonstandard operator families might perhaps choose to ignore this restriction, since there seems to be little semantic necessity for it.) This requirement is delegated to the `in_range` function so that the core code needn't understand what “less than zero” means for a particular data type.

An additional expectation is that `in_range` functions should, if practical, avoid throwing an error if  $base + offset$  or  $base - offset$  would overflow. The correct comparison result can be determined even if that value would be out of the data type's range. Note that if the data type includes concepts such as “infinity” or “NaN”, extra care may be needed to ensure that `in_range`'s results agree with the normal sort order of the operator family.

The results of the `in_range` function must be consistent with the sort ordering imposed by the operator family. To be precise, given any fixed values of *offset* and *sub*, then:

- If `in_range` with *less* = true is true for some *val1* and *base*, it must be true for every  $val2 \leq val1$  with the same *base*.
- If `in_range` with *less* = true is false for some *val1* and *base*, it must be false for every  $val2 \geq val1$  with the same *base*.
- If `in_range` with *less* = true is true for some *val* and *base1*, it must be true for every  $base2 \geq base1$  with the same *val*.
- If `in_range` with *less* = true is false for some *val* and *base1*, it must be false for every  $base2 \leq base1$  with the same *val*.

Analogous statements with inverted conditions hold when *less* = false.

If the type being ordered (*type1*) is collatable, the appropriate collation OID will be passed to the `in_range` function, using the standard `PG_GET_COLLATION()` mechanism.

`in_range` functions need not handle NULL inputs, and typically will be marked strict.

## `equalimage`

Optionally, a btree operator family may provide `equalimage` (“equality implies image equality”) support functions, registered under support function number 4. These functions allow the core code to determine when it is safe to apply the btree deduplication optimization. Currently, `equalimage` functions are only called when building or rebuilding an index.

An `equalimage` function must have the signature

`equalimage(opcintype oid) returns bool`

The return value is static information about an operator class and collation. Returning `true` indicates that the `order` function for the operator class is guaranteed to only return 0 (“arguments

are equal”) when its *A* and *B* arguments are also interchangeable without any loss of semantic information. Not registering an `equalimage` function or returning `false` indicates that this condition cannot be assumed to hold.

The *opcintype* argument is the `pg_type.oid` of the data type that the operator class indexes. This is a convenience that allows reuse of the same underlying `equalimage` function across operator classes. If *opcintype* is a collatable data type, the appropriate collation OID will be passed to the `equalimage` function, using the standard `PG_GET_COLLATION()` mechanism.

As far as the operator class is concerned, returning `true` indicates that deduplication is safe (or safe for the collation whose OID was passed to its `equalimage` function). However, the core code will only deem deduplication safe for an index when *every* indexed column uses an operator class that registers an `equalimage` function, and each function actually returns `true` when called.

Image equality is *almost* the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's `equalimage` function returns `true`, it is safe to assume that the `datum_image_eq()` C function will always agree with the operator class's `order` function (provided that the same collation OID is passed to both the `equalimage` and `order` functions).

The core code is fundamentally unable to deduce anything about the “equality implies image equality” status of an operator class within a multiple-data-type family based on details from other operator classes in the same family. Also, it is not sensible for an operator family to register a cross-type `equalimage` function, and attempting to do so will result in an error. This is because “equality implies image equality” status does not just depend on sorting/equality semantics, which are more or less defined at the operator family level. In general, the semantics that one particular data type implements must be considered separately.

The convention followed by the operator classes included with the core PostgreSQL distribution is to register a stock, generic `equalimage` function. Most operator classes register `btequalimage()`, which indicates that deduplication is safe unconditionally. Operator classes for collatable data types such as `text` register `btvarstrequalimage()`, which indicates that deduplication is safe with deterministic collations. Best practice for third-party extensions is to register their own custom function to retain control.

## options

Optionally, a B-tree operator family may provide `options` (“operator class specific options”) support functions, registered under support function number 5. These functions define a set of user-visible parameters that control operator class behavior.

An `options` support function must have the signature

```
options(relopts local_relopts *) returns void
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Currently, no B-Tree operator class has an `options` support function. B-tree doesn't allow flexible representation of keys like GiST, SP-GiST, GIN and BRIN do. So, `options` probably doesn't have much application in the current B-tree index access method. Nevertheless, this support function was added to B-tree for uniformity, and will probably find uses during further evolution of B-tree in PostgreSQL.

## skipsupport

Optionally, a btree operator family may provide a *skip support* function, registered under support function number 6. These functions give the B-tree code a way to iterate through every possible

value that can be represented by an operator class's underlying input type, in key space order. This is used by the core code when it applies the skip scan optimization. The APIs involved in this are defined in `src/include/utils/skipsupport.h`.

Operator classes that do not provide a skip support function are still eligible to use skip scan. The core code can still use its fallback strategy, though that might be suboptimal for some discrete types. It usually doesn't make sense (and may not even be feasible) for operator classes on continuous types to provide a skip support function.

It is not sensible for an operator family to register a cross-type `skipsupport` function, and attempting to do so will result in an error. This is because determining the next indexable value must happen by incrementing a value copied from an index tuple. The values generated must all be of the same underlying data type (the “skipped” index column's opclass input type).

## 65.1.4. Implementation

This section covers B-Tree index implementation details that may be of use to advanced users. See `src/backend/access/nbtree/README` in the source distribution for a much more detailed, internals-focused description of the B-Tree implementation.

### 65.1.4.1. B-Tree Structure

PostgreSQL B-Tree indexes are multi-level tree structures, where each level of the tree can be used as a doubly-linked list of pages. A single metapage is stored in a fixed position at the start of the first segment file of the index. All other pages are either leaf pages or internal pages. Leaf pages are the pages on the lowest level of the tree. All other levels consist of internal pages. Each leaf page contains tuples that point to table rows. Each internal page contains tuples that point to the next level down in the tree. Typically, over 99% of all pages are leaf pages. Both internal pages and leaf pages use the standard page format described in Section 66.6.

New leaf pages are added to a B-Tree index when an existing leaf page cannot fit an incoming tuple. A *page split* operation makes room for items that originally belonged on the overflowing page by moving a portion of the items to a new page. Page splits must also insert a new *downlink* to the new page in the parent page, which may cause the parent to split in turn. Page splits “cascade upwards” in a recursive fashion. When the root page finally cannot fit a new downlink, a *root page split* operation takes place. This adds a new level to the tree structure by creating a new root page that is one level above the original root page.

### 65.1.4.2. Bottom-up Index Deletion

B-Tree indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical table row; to an index, each tuple is an independent object that needs its own index entry. “Version churn” tuples may sometimes accumulate and adversely affect query latency and throughput. This typically occurs with UPDATE-heavy workloads where most individual updates cannot apply the HOT optimization. Changing the value of only one column covered by one index during an UPDATE *always* necessitates a new set of index tuples — one for *each and every* index on the table. Note in particular that this includes indexes that were not “logically modified” by the UPDATE. All indexes will need a successor physical index tuple that points to the latest version in the table. Each new tuple within each index will generally need to coexist with the original “updated” tuple for a short period of time (typically until shortly after the UPDATE transaction commits).

B-Tree indexes incrementally delete version churn index tuples by performing *bottom-up index deletion* passes. Each deletion pass is triggered in reaction to an anticipated “version churn page split”. This only happens with indexes that are not logically modified by UPDATE statements, where concentrated build up of obsolete versions in particular pages would occur otherwise. A page split will usually be avoided, though it's possible that certain implementation-level heuristics will fail to identify and delete even one garbage index tuple (in which case a page split or deduplication pass resolves the issue of an incoming new tuple not fitting on a leaf page). The worst-case number of versions that any index scan

must traverse (for any single logical row) is an important contributor to overall system responsiveness and throughput. A bottom-up index deletion pass targets suspected garbage tuples in a single leaf page based on *qualitative* distinctions involving logical rows and versions. This contrasts with the “top-down” index cleanup performed by autovacuum workers, which is triggered when certain *quantitative* table-level thresholds are exceeded (see Section 24.1.6).

### Note

Not all deletion operations that are performed within B-Tree indexes are bottom-up deletion operations. There is a distinct category of index tuple deletion: *simple index tuple deletion*. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's LP\_DEAD bit is already set). Like bottom-up index deletion, simple index deletion takes place at the point that a page split is anticipated as a way of avoiding the split.

Simple deletion is opportunistic in the sense that it can only take place when recent index scans set the LP\_DEAD bits of affected items in passing. Prior to PostgreSQL 14, the only category of B-Tree deletion was simple deletion. The main differences between it and bottom-up deletion are that only the former is opportunistically driven by the activity of passing index scans, while only the latter specifically targets version churn from UPDATES that do not logically modify indexed columns.

Bottom-up index deletion performs the vast majority of all garbage index tuple cleanup for particular indexes with certain workloads. This is expected with any B-Tree index that is subject to significant version churn from UPDATES that rarely or never logically modify the columns that the index covers. The average and worst-case number of versions per logical row can be kept low purely through targeted incremental deletion passes. It's quite possible that the on-disk size of certain indexes will never increase by even one single page/block despite *constant* version churn from UPDATES. Even then, an exhaustive “clean sweep” by a VACUUM operation (typically run in an autovacuum worker process) will eventually be required as a part of *collective* cleanup of the table and each of its indexes.

Unlike VACUUM, bottom-up index deletion does not provide any strong guarantees about how old the oldest garbage index tuple may be. No index can be permitted to retain “floating garbage” index tuples that became dead prior to a conservative cutoff point shared by the table and all of its indexes collectively. This fundamental table-level invariant makes it safe to recycle table TIDs. This is how it is possible for distinct logical rows to reuse the same table TID over time (though this can never happen with two logical rows whose lifetimes span the same VACUUM cycle).

### 65.1.4.3. Deduplication

A duplicate is a leaf page tuple (a tuple that points to a table row) where *all* indexed key columns have values that match corresponding column values from at least one other leaf page tuple in the same index. Duplicate tuples are quite common in practice. B-Tree indexes can use a special, space-efficient representation for duplicates when an optional technique is enabled: *deduplication*.

Deduplication works by periodically merging groups of duplicate tuples together, forming a single *posting list* tuple for each group. The column key value(s) only appear once in this representation. This is followed by a sorted array of TIDs that point to rows in the table. This significantly reduces the storage size of indexes where each value (or each distinct combination of column values) appears several times on average. The latency of queries can be reduced significantly. Overall query throughput may increase significantly. The overhead of routine index vacuuming may also be reduced significantly.

### Note

B-Tree deduplication is just as effective with “duplicates” that contain a NULL value, even though NULL values are never equal to each other according to the = member of any B-Tree

operator class. As far as any part of the implementation that understands the on-disk B-Tree structure is concerned, NULL is just another value from the domain of indexed values.

The deduplication process occurs lazily, when a new item is inserted that cannot fit on an existing leaf page, though only when index tuple deletion could not free sufficient space for the new item (typically deletion is briefly considered and then skipped over). Unlike GIN posting list tuples, B-Tree posting list tuples do not need to expand every time a new duplicate is inserted; they are merely an alternative physical representation of the original logical contents of the leaf page. This design prioritizes consistent performance with mixed read-write workloads. Most client applications will at least see a moderate performance benefit from using deduplication. Deduplication is enabled by default.

**CREATE INDEX** and **REINDEX** apply deduplication to create posting list tuples, though the strategy they use is slightly different. Each group of duplicate ordinary tuples encountered in the sorted input taken from the table is merged into a posting list tuple *before* being added to the current pending leaf page. Individual posting list tuples are packed with as many TIDs as possible. Leaf pages are written out in the usual way, without any separate deduplication pass. This strategy is well-suited to **CREATE INDEX** and **REINDEX** because they are once-off batch operations.

Write-heavy workloads that don't benefit from deduplication due to having few or no duplicate values in indexes will incur a small, fixed performance penalty (unless deduplication is explicitly disabled). The `deduplicate_items` storage parameter can be used to disable deduplication within individual indexes. There is never any performance penalty with read-only workloads, since reading posting list tuples is at least as efficient as reading the standard tuple representation. Disabling deduplication isn't usually helpful.

It is sometimes possible for unique indexes (as well as unique constraints) to use deduplication. This allows leaf pages to temporarily “absorb” extra version churn duplicates. Deduplication in unique indexes augments bottom-up index deletion, especially in cases where a long-running transaction holds a snapshot that blocks garbage collection. The goal is to buy time for the bottom-up index deletion strategy to become effective again. Delaying page splits until a single long-running transaction naturally goes away can allow a bottom-up deletion pass to succeed where an earlier deletion pass failed.

### Tip

A special heuristic is applied to determine whether a deduplication pass in a unique index should take place. It can often skip straight to splitting a leaf page, avoiding a performance penalty from wasting cycles on unhelpful deduplication passes. If you're concerned about the overhead of deduplication, consider setting `deduplicate_items = off` selectively. Leaving deduplication enabled in unique indexes has little downside.

Deduplication cannot be used in all cases due to implementation-level restrictions. Deduplication safety is determined when **CREATE INDEX** or **REINDEX** is run.

Note that deduplication is deemed unsafe and cannot be used in the following cases involving semantically significant differences among equal datums:

- `text`, `varchar`, and `char` cannot use deduplication when a *nondeterministic* collation is used. Case and accent differences must be preserved among equal datums.
- `numeric` cannot use deduplication. Numeric display scale must be preserved among equal datums.
- `jsonb` cannot use deduplication, since the `jsonb` B-Tree operator class uses `numeric` internally.
- `float4` and `float8` cannot use deduplication. These types have distinct representations for `-0` and `0`, which are nevertheless considered equal. This difference must be preserved.

There is one further implementation-level restriction that may be lifted in a future version of PostgreSQL:

- Container types (such as composite types, arrays, or range types) cannot use deduplication.

There is one further implementation-level restriction that applies regardless of the operator class or collation used:

- INCLUDE indexes can never use deduplication.

## 65.2. GiST Indexes

### 65.2.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project web site<sup>1</sup> and Marcel Kornacker's thesis, Access Methods for Next-Generation Database Systems<sup>2</sup>. The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site<sup>3</sup>.

### 65.2.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 65.1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

**Table 65.1. Built-in GiST Operator Classes**

| Name       | Indexable Operators | Ordering Operators  |
|------------|---------------------|---------------------|
| box_ops    | << (box, box)       | <-> (box, point)    |
|            | &< (box, box)       |                     |
|            | && (box, box)       |                     |
|            | &> (box, box)       |                     |
|            | >> (box, box)       |                     |
|            | ~= (box, box)       |                     |
|            | @> (box, box)       |                     |
|            | <@ (box, box)       |                     |
|            | &<  (box, box)      |                     |
|            | <<  (box, box)      |                     |
|            | >> (box, box)       |                     |
|            | &> (box, box)       |                     |
| circle_ops | << (circle, circle) | <-> (circle, point) |
|            | &< (circle, circle) |                     |
|            | &> (circle, circle) |                     |
|            | >> (circle, circle) |                     |
|            | <@ (circle, circle) |                     |

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

### 65.2.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are five methods that an index operator class for GiST must provide, and seven that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. Two optional methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree’s internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans, except when the `compress` method is omitted. The optional tenth method `options` is needed if the operator class has user-specified parameters. The optional eleventh method `sortsupport` is used to speed up building a GiST index. The optional twelfth method `stratnum` is used to translate compare types (from `src/include/access/cmptype.h`) into strategy numbers used by the operator class. This lets the core code look up operators for temporal constraint indexes.

#### `consistent`

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “*indexed\_column indexable\_op-*

*erator* *q*” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is true, a *recheck* flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If *recheck* = false then the index has tested the predicate condition exactly, whereas if *recheck* = true the row is only a candidate match. In that case the system will automatically evaluate the *indexable\_operator* against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type,
    smallint, oid, internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber)
    PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataTypes(entry->key);
    bool retval;

    /*
     * determine return value as a function of strategy, key and
     * query.
     *
     * Use GIST_LEAF(entry) to know where you're called in the
     * index tree,
     * which comes handy when supporting the = operator for
     * example (you could
     * check for non empty union() in non-leaf nodes and
     * equality in leaf
     * nodes).
     */

    *recheck = true; /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}
```

Here, *key* is an element in the index and *query* the value being looked up in the index. The *StrategyNumber* parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of *query* could vary with the operator, since it will be whatever type is on the right-hand side of the operator, which

might be different from the indexed data type appearing on the left-hand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the `consistent` function use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

## union

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *)
    PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
               *tmp,
               *old;
    int        numranges,
               i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataType(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we're dealing with a data type where `union(X, Y, Z) = union(union(X, Y), Z)`. It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the `union` function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The `union` function should return a pointer to newly `palloc()`ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the `union` function's first `internal` argument is actually a `GistEntryVector` pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the `union` function store the size of its result value into that variable, but this is no longer necessary.)

## `compress`

Converts a data item into a format suitable for physical storage in an index page. If the `compress` method is omitted, data items are stored in the index without modification.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data =
            palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */

        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset,
FALSE);
    }
    else
    {
        /* typically we needn't do anything with non-leaf
entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt *compressed\_data\_type* to the specific type you're converting to in order to compress your leaf nodes, of course.

## decompress

Converts the stored representation of a data item into a format that can be manipulated by the other GiST methods in the operator class. If the `decompress` method is omitted, it is assumed that the other GiST methods can work directly on the stored data format. (`decompress` is not necessarily the reverse of the `compress` method; in particular, if `compress` is lossy then it's impossible for `decompress` to exactly reconstruct the original data. `decompress` is not necessarily equivalent to `fetch`, either, since the other GiST methods might not require full reconstruction of the data.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}
```

The above skeleton is suitable for the case where no decompression is needed. (But, of course, omitting the method altogether is even easier, and is recommended in such cases.)

## penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least `penalty` in the tree. Values returned by `penalty` should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_penalty(internal, internal,
internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not
be strict
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);
}
```

```
    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

For historical reasons, the `penalty` function doesn't just return a `float` result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The `penalty` function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

### `picksplit`

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *)
    PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
```

```

unionR = NULL;

/* Initialize the raw entry vector. */
raw_entryvec = (GISTENTRY **) malloc(entryvec->n *
sizeof(void *));
for (i = FirstOffsetNumber; i <= maxoff; i =
OffsetNumberNext(i))
    raw_entryvec[i] = &(entryvec->vector[i]);

for (i = FirstOffsetNumber; i <= maxoff; i =
OffsetNumberNext(i))
{
    int          real_index = raw_entryvec[i] - entryvec-
>vector;

    tmp_union = DatumGetDataType(entryvec-
>vector[real_index].key);
    Assert(tmp_union != NULL);

    /*
     * Choose where to put the index entries and update
unionL and unionR
     * accordingly. Append the entries to either v->spl_left
or
     * v->spl_right, and care about the counters.
     */

    if (my_choice_is_left(unionL, curl, unionR, curr))
    {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL,
tmp_union);

        *left = real_index;
        ++left;
        ++(v->spl_nleft);
    }
    else
    {
        /*
         * Same on the right
         */
    }
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}

```

Notice that the `picksplit` function's result is delivered by modifying the passed-in `v` structure. The return value per se is ignored, though it's conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

## same

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type,
    internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool          *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}
```

For historical reasons, the `same` function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

## distance

Given an index entry `p` and a query value `q`, this function determines the index entry's “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_distance(internal, data_type,
    smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
```

```
    StrategyNumber strategy = (StrategyNumber)
PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
/* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
data_type *key = DatumGetDataType(entry->key);
double     retval;

/*
 * determine return value as a function of strategy, key and
query.
 */

    PG_RETURN_FLOAT8(retval);
}
```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator's return type must be `float8` or `float4`, and the distance function's result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that `distance` functions return these values.)

## fetch

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the opclass's compress function does nothing for leaf entries, the `fetch` method can return the argument as-is. Or, if the opclass does not have a compress function, the `fetch` method can be omitted as well, since it would necessarily be a no-op.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);
```

```
Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original
     datatype.
     */

    /* fill *retval from fetched_data. */
    gistentryinit(retval, PointerGetDatum(converted_datum),
                  entry->rel, entry->page, entry->offset,
                  FALSE);

    PG_RETURN_POINTER(retval);
}
```

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a `fetch` function.

## options

Allows definition of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

An example implementation of `my_options()` and parameters use from other support functions are given below:

```
typedef enum MyEnumType
{
    MY_ENUM_ON,
    MY_ENUM_OFF,
    MY_ENUM_AUTO
} MyEnumType;

typedef struct
{
    int32    vl_len_;      /* varlena header (do not touch
directly!) */
    int      int_param;    /* integer parameter */
    double   real_param;   /* real parameter */
}
```

```
    MyEnumType enum_param; /* enum parameter */
    int      str_param; /* string parameter */
} MyOptionsStruct;

/* String representation of enum values */
static relopt_enum_elt_def myEnumValues[] =
{
    {"on", MY_ENUM_ON},
    {"off", MY_ENUM_OFF},
    {"auto", MY_ENUM_AUTO},
    {(const char *) NULL} /* list terminator */
};

static char *str_param_default = "default";

/*
 * Sample validator: checks that string is not longer than 8
 * bytes.
 */
static void
validate_my_string_relopt(const char *value)
{
    if (strlen(value) > 8)
        ereport(ERROR,
                (errcode(ERRCODE_INVALID_PARAMETER_VALUE),
                 errmsg("str_param must be at most 8 bytes")));
}

/*
 * Sample filler: switches characters to lower case.
 */
static Size
fill_my_string_relopt(const char *value, void *ptr)
{
    char    *tmp = str_tolower(value, strlen(value),
                                DEFAULT_COLLATION_OID);
    int      len = strlen(tmp);

    if (ptr)
        strcpy(ptr, tmp);

    pfree(tmp);
    return len + 1;
}

PG_FUNCTION_INFO_V1(my_options);

Datum
my_options(PG_FUNCTION_ARGS)
{
    local_relopts *relopts = (local_relopts *)
        PG_GETARG_POINTER(0);

    init_local_reloptions(relopts, sizeof(MyOptionsStruct));
    add_local_int_reloption(relopts, "int_param", "integer
parameter",
                            100, 0, 1000000,
```

```

                                offsetof(MyOptionsStruct,
int_param));
    add_local_real_reloption(relopts, "real_param", "real
parameter",
                                1.0, 0.0, 1000000.0,
                                offsetof(MyOptionsStruct,
real_param));
    add_local_enum_reloption(relopts, "enum_param", "enum
parameter",
                                myEnumValues, MY_ENUM_ON,
                                "Valid values are: \"on\", \"off\"
and \"auto\".",
                                offsetof(MyOptionsStruct,
enum_param));
    add_local_string_reloption(relopts, "str_param", "string
parameter",
                                str_param_default,
                                &validate_my_string_relopt,
                                &fill_my_string_relopt,
                                offsetof(MyOptionsStruct,
str_param));

    PG_RETURN_VOID();
}

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    int    int_param = 100;
    double real_param = 1.0;
    MyEnumType enum_param = MY_ENUM_ON;
    char    *str_param = str_param_default;

    /*
     * Normally, when opclass contains 'options' method, then
     * options are always
     * passed to support functions. However, if you add
     * 'options' method to
     * existing opclass, previously defined indexes have no
     * options, so the
     * check is required.
     */
    if (PG_HAS_OPCLASS_OPTIONS())
    {
        MyOptionsStruct *options = (MyOptionsStruct *)
PG_GET_OPCLASS_OPTIONS();

        int_param = options->int_param;
        real_param = options->real_param;
        enum_param = options->enum_param;
        str_param = GET_STRING_RELOPTION(options, str_param);
    }

    /* the rest implementation of support function */
}

```

Since the representation of the key in GiST is flexible, it may depend on user-specified parameters. For instance, the length of key signature may be specified. See `gtsvector_options()` for example.

### `sortsupport`

Returns a comparator function to sort data in a way that preserves locality. It is used by `CREATE INDEX` and `REINDEX` commands. The quality of the created index depends on how well the sort order determined by the comparator function preserves locality of the inputs.

The `sortsupport` method is optional. If it is not provided, `CREATE INDEX` builds the index by inserting each tuple to the tree using the `penalty` and `picksplit` functions, which is much slower.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_sortsupport(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `SortSupport` struct. At a minimum, the function must fill in its comparator field. The comparator takes three arguments: two `Datums` to compare, and a pointer to the `SortSupport` struct. The `Datums` are the two indexed values in the format that they are stored in the index; that is, in the format returned by the `compress` method. The full API is defined in `src/include/utils/sortsupport.h`.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_sortsupport);

static int
my_fastcmp(Datum x, Datum y, SortSupport ssup)
{
    /* establish order between x and y by computing some sorting
    value z */

    int z1 = ComputeSpatialCode(x);
    int z2 = ComputeSpatialCode(y);

    return z1 == z2 ? 0 : z1 > z2 ? 1 : -1;
}

Datum
my_sortsupport(PG_FUNCTION_ARGS)
{
    SortSupport ssup = (SortSupport) PG_GETARG_POINTER(0);

    ssup->comparator = my_fastcmp;
    PG_RETURN_VOID();
}
```

### `translate_cmptype`

Given a `CompareType` value from `src/include/access/cmptype.h`, returns a strategy number used by this operator class for matching functionality. The function should return `InvalidStrategy` if the operator class has no matching strategy.

This is used for temporal index constraints (i.e., `PRIMARY KEY` and `UNIQUE`). If the operator class provides this function and it returns results for `COMPARE_EQ`, it can be used in the non-`WITHOUT OVERLAPS` part(s) of an index constraint.

This support function corresponds to the index access method callback function `amtranslate_cmptype` (see Section 63.2). The `amtranslate_cmptype` callback function for GiST indexes merely calls down to the `translate_cmptype` support function of the respective operator family, since the GiST index access method has no fixed strategy numbers itself.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_translate_cmptype(integer)
RETURNS smallint
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the operator family registration must look like this:

```
ALTER OPERATOR FAMILY my_opfamily USING gist ADD
    FUNCTION 12 ("any", "any") my_translate_cmptype(int);
```

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_translate_cmptype);

Datum
my_translate_cmptype(PG_FUNCTION_ARGS)
{
    CompareType cmptype = PG_GETARG_INT32(0);
    StrategyNumber ret = InvalidStrategy;

    switch (cmptype)
    {
        case COMPARE_EQ:
            ret = BTEqualStrategyNumber;
    }

    PG_RETURN_UINT16(ret);
}
```

One translation function is provided by PostgreSQL: `gist_translate_cmptype_common` is for operator classes that use the `RT*StrategyNumber` constants. The `btree_gist` extension defines a second translation function, `gist_translate_cmptype_btree`, for operator classes that use the `BT*StrategyNumber` constants.

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about pfree'ing everything you palloc. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.

## 65.2.4. Implementation

### 65.2.4.1. GiST Index Build Methods

The simplest way to build a GiST index is just to insert all the entries, one by one. This tends to be slow for large indexes, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, a lot of random I/O will be needed. PostgreSQL supports two alternative methods for initial build of a GiST index: *sorted* and *buffered* modes.

The sorted method is only available if each of the opclasses used by the index provides a `sortsupport` function, as described in Section 65.2.3. If they do, this method is usually the best, so it is used by default.

The buffered method works by not inserting tuples directly into the index right away. It can dramatically reduce the amount of random I/O needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as a whole does not.

The buffered method needs to call the `penalty` function more often than the simple method does, which consumes some extra CPU resources. Also, the buffers need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

If sorting is not possible, then by default a GiST index build switches to the buffering method when the index size reaches `effective_cache_size`. Buffering can be manually forced or prevented by the `buffering` parameter to the `CREATE INDEX` command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

## 65.2.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see `src/backend/access/gist/gistproc.c`). The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of `int4` values

`ltree`

Indexing for tree-like structures

`pg_trgm`

Text similarity using trigram matching

seg

Indexing for “float ranges”

## 65.3. SP-GiST Indexes

### 65.3.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site<sup>4</sup>. The SP-GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site<sup>5</sup>.

### 65.3.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 65.2.

**Table 65.2. Built-in SP-GiST Operator Classes**

| Name     | Indexable Operators | Ordering Operators |
|----------|---------------------|--------------------|
| box_ops  | << (box, box)       | <-> (box, point)   |
|          | &< (box, box)       |                    |
|          | &> (box, box)       |                    |
|          | >> (box, box)       |                    |
|          | <@ (box, box)       |                    |
|          | @> (box, box)       |                    |
|          | ~= (box, box)       |                    |
|          | && (box, box)       |                    |
|          | <<  (box, box)      |                    |
|          | &<  (box, box)      |                    |
|          | &> (box, box)       |                    |
|          | >> (box, box)       |                    |
| inet_ops | << (inet, inet)     |                    |
|          | <<= (inet, inet)    |                    |
|          | >> (inet, inet)     |                    |

|                | ~= (point, point)          |                      |
|                | <@ (point, box)            |                      |
| range_ops      | = (anyrange, anyrange)     |                      |
|                | &&<br>(anyrange, anyrange) |                      |
|                | @> (anyrange, anyelement)  |                      |
|                | @><br>(anyrange, anyrange) |                      |
|                | <@<br>(anyrange, anyrange) |                      |

| Name     | Indexable Operators         | Ordering Operators |
|----------|-----------------------------|--------------------|
|          | <<<br>(anyrange, anyrange)  |                    |
|          | >><br>(anyrange, anyrange)  |                    |
|          | &<<br>(anyrange, anyrange)  |                    |
|          | &><br>(anyrange, anyrange)  |                    |
|          | - -<br>(anyrange, anyrange) |                    |
| text_ops | = (text, text)              |                    |
|          | < (text, text)              |                    |
|          | <= (text, text)             |                    |
|          | > (text, text)              |                    |
|          | >= (text, text)             |                    |
|          | ~<~ (text, text)            |                    |
|          | ~<=~ (text, text)           |                    |
|          | ~>=~ (text, text)           |                    |
|          | ~>~ (text, text)            |                    |
|          | ^@ (text, text)             |                    |

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops` and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k-NN) search over indexed point or polygon data sets.

### 65.3.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree usually contain values of the same data type as the indexed column, although it is also possible for them to contain lossy representations of the indexed column. Leaf tuples stored at the root level will directly represent the original indexed data value, but leaf tuples at lower levels might contain only a partial value, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

When an SP-GiST index is created with `INCLUDE` columns, the values of those columns are also stored in leaf tuples. The `INCLUDE` columns are of no concern to the SP-GiST operator class, so they are not discussed further here.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more *nodes*, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a *label* that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can

omit the node labels, if it works with a fixed set of nodes for all inner tuples; see Section 65.3.4.2.) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

### Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and two are optional. All five mandatory methods follow the convention of accepting two `internal` arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the mandatory methods just return `void`, since all their results appear in the output struct; but `leaf_consistent` returns a `boolean` result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method. The optional sixth method `compress` accepts a `datum` to be indexed as the only argument and returns a value suitable for physical storage in a leaf tuple. The optional seventh method `options` accepts an `internal` pointer to a C struct, where opclass-specific parameters should be placed, and returns `void`.

The five mandatory user-defined methods are:

#### `config`

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```
typedef struct spgConfigIn
{
    Oid      attType;          /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid      prefixType;       /* Data type of inner-tuple
prefixes */
    Oid      labelType;        /* Data type of inner-tuple node
labels */
}
```

```
    Oid          leafType;          /* Data type of leaf-tuple
values */
    bool         canReturnData;     /* Opclass can reconstruct
original data */
    bool         longValuesOK;     /* Opclass can cope with values
> 1 page */
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 65.3.4.1).

`leafType` should match the index storage type defined by the operator class's `opkeytype` catalog entry. (Note that `opkeytype` can be zero, implying the storage type is the same as the operator class's input type, which is the most common situation.) For reasons of backward compatibility, the `config` method can set `leafType` to some other value, and that value will be used; but this is deprecated since the index contents are then incorrectly identified in the catalogs. Also, it's permissible to leave `leafType` uninitialized (zero); that is interpreted as meaning the index storage type derived from `opkeytype`.

When `attType` and `leafType` are different, the optional method `compress` must be provided. Method `compress` is responsible for transformation of datums to be indexed from `attType` to `leafType`.

## choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```
typedef struct spgChooseIn
{
    Datum        datum;            /* original datum to be indexed
*/
    Datum        leafDatum;        /* current datum to be stored at
leaf */
    int          level;            /* current level (counting from
zero) */

    /* Data from current inner tuple */
    bool         allTheSame;       /* tuple is marked all-the-same?
*/
    bool         hasPrefix;        /* tuple has a prefix? */
    Datum        prefixDatum;      /* if so, the prefix value */
    int          nNodes;           /* number of nodes in the inner
tuple */
}
```

---

```

    Datum      *nodeLabels;    /* node label values (NULL if
none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,          /* descend into existing node */
    spgAddNode,                /* add a node to the inner tuple
*/
    spgSplitTuple              /* split inner tuple (change its
prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see
above */
    union
    {
        struct                /* results for spgMatchNode */
        {
            int                nodeN;    /* descend to this node
(index from 0) */
            int                levelAdd; /* increment level by this
much */
            Datum              restDatum; /* new leaf datum */
        } matchNode;
        struct                /* results for spgAddNode */
        {
            Datum              nodeLabel; /* new node's label */
            int                nodeN;    /* where to insert it (index
from 0) */
        } addNode;
        struct                /* results for spgSplitTuple */
        {
            /* Info to form new upper-level inner tuple with one
child tuple */
            bool                prefixHasPrefix; /* tuple should have
a prefix? */
            Datum              prefixPrefixDatum; /* if so, its value
*/
            int                prefixNNodes; /* number of nodes
*/
            Datum              *prefixNodeLabels; /* their labels (or
NULL for
                                * no labels) */
            int                childNodeN; /* which node gets
child tuple */

            /* Info to form new lower-level inner tuple with all
old nodes */
            bool                postfixHasPrefix; /* tuple should have
a prefix? */
            Datum              postfixPrefixDatum; /* if so, its value
*/
        } splitTuple;
    } result;
} spgChooseOut;

```

---

`datum` is the original datum of `spgConfigIn.attType` type that was to be inserted into the index. `leafDatum` is a value of `spgConfigOut.leafType` type, which is initially a result of method `compress` applied to `datum` when method `compress` is provided, or the same value as `datum` otherwise. `leafDatum` can change at lower levels of the tree if the `choose` or `picksplit` methods change it. When the insertion search reaches a leaf page, the current value of `leafDatum` is what will be stored in the newly created leaf tuple. `level` is the current inner tuple's level, starting at zero for the root level. `allTheSame` is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 65.3.4.3). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if there are no labels.

The `choose` function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set `resultType` to `spgMatchNode`. Set `nodeN` to the index (from zero) of that node in the node array. Set `levelAdd` to the increment in `level` caused by descending through that node, or leave it as zero if the operator class does not use levels. Set `restDatum` to equal `leafDatum` if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as `leafDatum` at the next level.

If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed. Set `prefixNNodes` to the number of nodes needed in the new tuple, and set `prefixNodeLabels` to a palloc'd array holding their labels, or to NULL if node labels are not required. Note that the total size of the new upper tuple must be no more than the total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set `childNodeN` to the index (from zero) of the node that will downlink to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the downlink node's label (if any) must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call may return an `spgAddNode` result, if no suitable node was created by the `spgSplitTuple` action. Eventually `choose` must return `spgMatchNode` to allow the insertion to descend to the next level.

### `picksplit`

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS
void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int          nTuples;          /* number of leaf tuples */
    Datum        *datums;          /* their datums (array of length
nTuples) */
    int          level;           /* current level (counting from
zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool         hasPrefix;        /* new inner tuple should have a
prefix? */
    Datum        prefixDatum;      /* if so, its value */

    int          nNodes;          /* number of nodes for new inner
tuple */
    Datum        *nodeLabels;      /* their labels (or NULL for no
labels) */

    int          *mapTuplesToNodes; /* node index for each leaf
tuple */
    Datum        *leafTupleDatums; /* datum to store in each
new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values of `spgConfigOut.leafType` type. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values, or to NULL if node labels are not required. Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for palloc'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See Section 65.3.4.3 for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 65.3.4.1 for more information.

### `inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS
void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgInnerConsistentIn
{
    ScanKey      scankeys;          /* array of operators and
comparison values */
    ScanKey      orderbys;          /* array of ordering operators
and comparison
                                   * values */
    int          nkeys;              /* length of scankeys array */
    int          norderbys;         /* length of orderbys array */

    Datum        reconstructedValue; /* value reconstructed
at parent */
    void         *traversalValue;    /* opclass-specific traverse
value */
    MemoryContext traversalMemoryContext; /* put new traverse
values here */
    int          level;              /* current level (counting from
zero) */
    bool         returnData;         /* original data must be
returned? */

    /* Data from current inner tuple */
    bool         allTheSame;         /* tuple is marked all-the-same?
*/
    bool         hasPrefix;          /* tuple has a prefix? */
    Datum        prefixDatum;        /* if so, the prefix value */
    int          nNodes;             /* number of nodes in the inner
tuple */
    Datum        *nodeLabels;        /* node label values (NULL if
none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int          nNodes;             /* number of child nodes to be
visited */
    int          *nodeNumbers;       /* their indexes in the node
array */
    int          *levelAdds;         /* increment level by this much
for each */
    Datum        *reconstructedValues; /* associated
reconstructed values */
    void         **traversalValues;  /* opclass-specific
traverse values */
    double       **distances;        /* associated distances
*/
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes ordering operators (if any) in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 65.3.4.3). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. The reconstructed values are assumed to be of type `spgConfigOut.leafType`. (However, since the core system will do nothing with them except possibly copy them, it is sufficient for them to have the same `typlen` and `typbyval` properties as `leafType`.) If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as NULL. Note that the `inner_consistent` function is responsible for `palloc'ing` the `nodeNumbers`, `levelAdds`, `distances`, `reconstructedValues`, and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single `palloc'd` chunk.

### `leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS
bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn
{
    ScanKey      scankeys;          /* array of operators and
    comparison values */

```

```

    ScanKey    orderbys;        /* array of ordering operators
and comparison                                * values */
    int        nkeys;          /* length of scankeys array */
    int        norderbys;      /* length of orderbys array */

    Datum      reconstructedValue; /* value reconstructed
at parent */
    void      *traversalValue; /* opclass-specific traverse
value */
    int        level;          /* current level (counting from
zero) */
    bool       returnData;     /* original data must be
returned? */

    Datum      leafDatum;      /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum      leafValue;      /* reconstructed original
data, if any */
    bool       recheck;        /* set true if operator must
be rechecked */
    bool       recheckDistances; /* set true if distances must
be rechecked */
    double     *distances;     /* associated distances */
} spgLeafConsistentOut;

```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes the ordering operators in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value of `spgConfigOut.leafType` stored in the current leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true case, if `returnData` is true then `leafValue` must be set to the value (of type `spgConfigIn.attType`) originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array. Leave it NULL otherwise. If at least one of returned distances is not exact, set `recheckDistances` to true. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined methods are:

### Datum compress(Datum in)

Converts a data item into a format suitable for physical storage in a leaf tuple of the index. It accepts a value of type `spgConfigIn.attType` and returns a value of type `spgConfigOut.leafType`. The output value must not contain an out-of-line TOAST pointer.

Note: the `compress` method is only applied to values to be stored. The consistent methods receive query `scankeys` unchanged, without transformation using `compress`.

### options

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about `pfree`'ing everything you `palloc`. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

## 65.3.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

### 65.3.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to true only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the

set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 65.3.4.3.

When `longValuesOK` is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of `choose` method calls.

### 65.3.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array, and likewise the `choose` function can return NULL for the `prefixNodeLabels` array during a `spgSplitTuple` action. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases.

### 65.3.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

## 65.3.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST, as described in Table 65.2. Look into `src/backend/access/spgist/` and `src/backend/utils/adt/` to see the code.

## 65.4. GIN Indexes

### 65.4.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website<sup>6</sup>.

## 65.4.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 65.3. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

**Table 65.3. Built-in GIN Operator Classes**

| Name           | Indexable Operators     |
|----------------|-------------------------|
| array_ops      | && (anyarray, anyarray) |
|                | @> (anyarray, anyarray) |
|                | <@ (anyarray, anyarray) |
|                | = (anyarray, anyarray)  |
| jsonb_ops      | @> (jsonb, jsonb)       |
|                | @? (jsonb, jsonpath)    |
|                | @@ (jsonb, jsonpath)    |
|                | ? (jsonb, text)         |
|                | ?  (jsonb, text[])      |
|                | ?& (jsonb, text[])      |
| jsonb_path_ops | @> (jsonb, jsonb)       |
|                | @? (jsonb, jsonpath)    |
|                | @@ (jsonb, jsonpath)    |
| tsvector_ops   | @@ (tsvector, tsquery)  |

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

## 65.4.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

<sup>6</sup> <http://www.sai.msu.su/~megeera/wiki/Gin>

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

```
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

```
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool  
**pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see Section 36.16.2). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the `query` contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys` `bool`s and store its address at `*pmatch`. Each element of the array should be set to true if the corresponding key requires partial match, false if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` pointers and store its address at `*extra_data`, then store whatever it wants into the individual pointers. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not require extra data. If `*extra_data` is set, the whole array is passed to the `consistent` method, and the appropriate element to the `comparePartial` method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a Boolean `consistent` function, and a ternary `triConsistent` function. `triConsistent` covers the functionality of both, so providing `triConsistent` alone is sufficient. However, if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the Boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32
nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool
nullFlags[])
```

Returns true if an indexed item satisfies the query operator with strategy number `n` (or might satisfy it, if the `recheck` indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The `check` array has length `nkeys`, which is the same as the number of keys previously returned by `extractQuery` for this `query` datum. Each element of the `check` array is true if the indexed item contains the corresponding query key, i.e., if `(check[i] == true)` the *i*-th key of the `extractQuery` result array is present in the indexed item. The original `query` datum is passed in case the `consistent` method needs to consult it, and so are the `queryKeys[]` and `nullFlags[]` arrays previously returned by `extractQuery`. `extra_data` is the extra-data array returned by `extractQuery`, or NULL if none.

When `extractQuery` returns a null key in `queryKeys[]`, the corresponding `check[]` element is true if the indexed item contains a null key; that is, the semantics of `check[]` are like `IS NOT DISTINCT FROM`. The `consistent` function can examine the corresponding `nullFlags[]` element if it needs to tell the difference between a regular value match and a null match.

On success, `*recheck` should be set to true if the heap tuple needs to be rechecked against the query operator, or false if the index test is exact. That is, a false return value guarantees that the heap tuple does not match the query; a true return value with `*recheck` set to false guarantees that the heap tuple does match the query; and a true return value with `*recheck` set to true means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNum-
ber n, Datum query, int32 nkeys, Pointer extra_data[], Datum
queryKeys[], bool nullFlags[])
```

`triConsistent` is similar to `consistent`, but instead of Booleans in the `check` vector, there are three possible values for each key: `GIN_TRUE`, `GIN_FALSE` and `GIN_MAYBE`. `GIN_FALSE` and `GIN_TRUE` have the same meaning as regular Boolean values, while `GIN_MAYBE` means that the presence of that key is not known. When `GIN_MAYBE` values are present, the function should only return `GIN_TRUE` if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return `GIN_FALSE` only if the item certainly does not match, whether or not it contains the `GIN_MAYBE` keys. If the result depends on the `GIN_MAYBE` entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return `GIN_MAYBE`.

When there are no `GIN_MAYBE` values in the `check` vector, a `GIN_MAYBE` return value is the equivalent of setting the `recheck` flag in the Boolean `consistent` function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default btree operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the btree operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

```
int comparePartial(Datum partial_key, Datum key, StrategyNumber n,
Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS( )` and `PG_GET_OPCLASS_OPTIONS( )` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See Section 65.4.4.2 for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

## 65.4.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. Figure 65.1 illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

**Figure 65.1. GIN Internals**

#### 65.4.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See `CREATE INDEX` for details.

#### 65.4.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

#### 65.4.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

When `fastupdate` is enabled for GIN (see Section 65.4.4.1 for details), the penalty is less than when it is not. But for very large updates it may still be best to drop and recreate the index.

#### `maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

#### `gin_pending_list_limit`

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

#### `gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

## 65.4.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

## 65.4.7. Examples

The core PostgreSQL distribution includes the GIN operator classes previously shown in Table 65.3. The following `contrib` modules also contain GIN operator classes:

#### `btree_gin`

B-tree equivalent functionality for several data types

#### `hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

## 65.5. BRIN Indexes

### 65.5.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table.

BRIN works in terms of *block ranges* (or “page ranges”). A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

#### 65.5.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, the range that the new page belongs to does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating the initial summary for that range.

There are several ways to trigger the initial summarization of a page range. If the table is vacuumed, either manually or by autovacuum, all existing unsummarized page ranges are summarized. Also, if the index's `autosummarize` parameter is enabled, which it isn't by default, whenever autovacuum runs in that database, summarization will occur for all unsummarized page ranges that have been filled, regardless of whether the table itself is processed by autovacuum; see below.

Lastly, the following functions can be used (while these functions run, `search_path` is temporarily changed to `pg_catalog`, `pg_temp`):

`brin_summarize_new_values(regclass)` which summarizes all unsummarized ranges;

`brin_summarize_range(regclass, bigint)` which summarizes only the range containing the given page, if it is unsummarized.

When autosummarization is enabled, a request is sent to `autovacuum` to execute a targeted summarization for a block range when an insertion is detected for the first item of the first page of the next block range, to be fulfilled the next time an autovacuum worker finishes running in the same database. If the request queue is full, the request is not recorded and a message is sent to the server log:

```
LOG: request for BRIN range summarization for index "brin_wi_idx"
page 128 was not recorded
```

When this happens, the range will remain unsummarized until the next regular vacuum run on the table, or one of the functions mentioned above are invoked.

Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed. See Section 9.28.8 for details.

## 65.5.2. Built-in Operator Classes

The core PostgreSQL distribution includes the BRIN operator classes shown in Table 65.4.

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range. The *bloom* operator classes build a Bloom filter for all values in the range. The *minmax-multi* operator classes store multiple minimum and maximum values, representing values appearing in the indexed column within the range.

**Table 65.4. Built-in BRIN Operator Classes**

| Name              | Indexable Operators     |
|-------------------|-------------------------|
| bit_minmax_ops    | = (bit,bit)             |
|                   | < (bit,bit)             |
|                   | > (bit,bit)             |
|                   | <= (bit,bit)            |
|                   | >= (bit,bit)            |
| box_inclusion_ops | @> (box,point)          |
|                   | << (box,box)            |
|                   | &< (box,box)            |
|                   | &> (box,box)            |
|                   | >> (box,box)            |
|                   | <@ (box,box)            |
|                   | @> (box,box)            |
|                   | ~= (box,box)            |
|                   | && (box,box)            |
|                   | <<  (box,box)           |
|                   | &<  (box,box)           |
|                   | &> (box,box)            |
|                   | >> (box,box)            |
| bpchar_bloom_ops  | = (character,character) |
| bpchar_minmax_ops | = (character,character) |

| Name                    | Indexable Operators       |
|-------------------------|---------------------------|
|                         | < (character, character)  |

|                       | < (varbit,varbit)   |
|                       | > (varbit,varbit)   |
|                       | <= (varbit,varbit)  |
|                       | >= (varbit,varbit)  |

### 65.5.2.1. Operator Class Parameters

Some of the built-in operator classes allow specifying parameters affecting behavior of the operator class. Each operator class has its own set of allowed parameters. Only the `bloom` and `minmax-multi` operator classes allow specifying parameters:

`bloom` operator classes accept these parameters:

`n_distinct_per_range`

Defines the estimated number of distinct non-null values in the block range, used by BRIN bloom indexes for sizing of the Bloom filter. It behaves similarly to `n_distinct` option for `ALTER TABLE`. When set to a positive value, each block range is assumed to contain this number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, the number of distinct non-null values is assumed to grow linearly with the maximum possible number of tuples in the block range (about 290 rows per block). The default value is `-0.1`, and the minimum number of distinct non-null values is 16.

`false_positive_rate`

Defines the desired false positive rate used by BRIN bloom indexes for sizing of the Bloom filter. The values must be between 0.0001 and 0.25. The default value is 0.01, which is 1% false positive rate.

`minmax-multi` operator classes accept these parameters:

`values_per_range`

Defines the maximum number of values stored by BRIN minmax indexes to summarize a block range. Each value may represent either a point, or a boundary of an interval. Values must be between 8 and 256, and the default value is 32.

## 65.5.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

`BrinOpcInfo *opcInfo(Oid type_oid)`

Returns internal information about the indexed columns' summary data. The return value must point to a palloc'd `BrinOpcInfo`, which has this definition:

```
typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this
    opclass */
    uint16      oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void        *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_tpcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support functions during an index scan.

`bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey *keys, int nkeys)`

Returns whether all the `ScanKey` entries are consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. Multiple scan keys for the same attribute may be passed at once; the number of entries is determined by the `nkeys` parameter.

`bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)`

Returns whether the `ScanKey` is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. This is an older backward-compatible variant of the `consistent` function.

`bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)`

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

`bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)`

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

`void options(local_relopts *relopts)`

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS( )` and `PG_GET_OPCLASS_OPTIONS( )` macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.

The core distribution includes support for four types of operator classes: minmax, minmax-multi, inclusion and bloom. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in Table 65.5. All operator class members (functions and operators) are mandatory.

**Table 65.5. Function and Support Numbers for Minmax Operator Classes**

| Operator class member | Object                                                   |
|-----------------------|----------------------------------------------------------|
| Support Function 1    | internal function <code>brin_minmax_opcinfo( )</code>    |
| Support Function 2    | internal function <code>brin_minmax_add_value( )</code>  |
| Support Function 3    | internal function <code>brin_minmax_consistent( )</code> |
| Support Function 4    | internal function <code>brin_minmax_union( )</code>      |
| Operator Strategy 1   | operator less-than                                       |
| Operator Strategy 2   | operator less-than-or-equal-to                           |
| Operator Strategy 3   | operator equal-to                                        |
| Operator Strategy 4   | operator greater-than-or-equal-to                        |
| Operator Strategy 5   | operator greater-than                                    |

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in Table 65.6. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

**Table 65.6. Function and Support Numbers for Inclusion Operator Classes**

| Operator class member | Object                                                      | Dependency |
|-----------------------|-------------------------------------------------------------|------------|
| Support Function 1    | internal function <code>brin_inclusion_opcinfo( )</code>    |            |
| Support Function 2    | internal function <code>brin_inclusion_add_value( )</code>  |            |
| Support Function 3    | internal function <code>brin_inclusion_consistent( )</code> |            |
| Support Function 4    | internal function <code>brin_inclusion_union( )</code>      |            |

| Operator class member           | Object                                                               | Dependency           |
|---------------------------------|----------------------------------------------------------------------|----------------------|
| Support Function 11             | function to merge two elements                                       |                      |
| Support Function 12             | optional function to check whether two elements are mergeable        |                      |
| Support Function 13             | optional function to check if an element is contained within another |                      |
| Support Function 14             | optional function to check whether an element is empty               |                      |
| Operator Strategy 1             | operator left-of                                                     | Operator Strategy 4  |
| Operator Strategy 2             | operator does-not-extend-to-the-right-of                             | Operator Strategy 5  |
| Operator Strategy 3             | operator overlaps                                                    |                      |
| Operator Strategy 4             | operator does-not-extend-to-the-left-of                              | Operator Strategy 1  |
| Operator Strategy 5             | operator right-of                                                    | Operator Strategy 2  |
| Operator Strategy 6, 18         | operator same-as-or-equal-to                                         | Operator Strategy 7  |
| Operator Strategy 7, 16, 24, 25 | operator contains-or-equal-to                                        |                      |
| Operator Strategy 8, 26, 27     | operator is-contained-by-or-equal-to                                 | Operator Strategy 3  |
| Operator Strategy 9             | operator does-not-extend-above                                       | Operator Strategy 11 |
| Operator Strategy 10            | operator is-below                                                    | Operator Strategy 12 |
| Operator Strategy 11            | operator is-above                                                    | Operator Strategy 9  |
| Operator Strategy 12            | operator does-not-extend-below                                       | Operator Strategy 10 |
| Operator Strategy 20            | operator less-than                                                   | Operator Strategy 5  |
| Operator Strategy 21            | operator less-than-or-equal-to                                       | Operator Strategy 5  |
| Operator Strategy 22            | operator greater-than                                                | Operator Strategy 1  |
| Operator Strategy 23            | operator greater-than-or-equal-to                                    | Operator Strategy 1  |

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the **STORAGE** parameter. The return value of the union function should match the **STORAGE** data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

To write an operator class for a data type that implements only an equality operator and supports hashing, it is possible to use the bloom support procedures alongside the corresponding operators, as shown in Table 65.7. All operator class members (procedures and operators) are mandatory.

**Table 65.7. Procedure and Support Numbers for Bloom Operator Classes**

| Operator class member | Object                                              |
|-----------------------|-----------------------------------------------------|
| Support Procedure 1   | internal function <code>brin_bloom_opcinfo()</code> |

| Operator class member | Object                                                 |
|-----------------------|--------------------------------------------------------|
| Support Procedure 2   | internal function <code>brin_bloom_add_value()</code>  |
| Support Procedure 3   | internal function <code>brin_bloom_consistent()</code> |
| Support Procedure 4   | internal function <code>brin_bloom_union()</code>      |
| Support Procedure 5   | internal function <code>brin_bloom_options()</code>    |
| Support Procedure 11  | function to compute hash of an element                 |
| Operator Strategy 1   | operator equal-to                                      |

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept one argument with the same data type as the operator class, and return a hash of the value.

The minmax-multi operator class is also intended for data types implementing a totally ordered set, and may be seen as a simple extension of the minmax operator class. While minmax operator class summarizes values from each block range into a single contiguous interval, minmax-multi allows summarization into multiple smaller intervals to improve handling of outlier values. It is possible to use the minmax-multi support procedures alongside the corresponding operators, as shown in Table 65.8. All operator class members (procedures and operators) are mandatory.

**Table 65.8. Procedure and Support Numbers for minmax-multi Operator Classes**

| Operator class member | Object                                                              |
|-----------------------|---------------------------------------------------------------------|
| Support Procedure 1   | internal function <code>brin_minmax_multi_opcinfo()</code>          |
| Support Procedure 2   | internal function <code>brin_minmax_multi_add_value()</code>        |
| Support Procedure 3   | internal function <code>brin_minmax_multi_consistent()</code>       |
| Support Procedure 4   | internal function <code>brin_minmax_multi_union()</code>            |
| Support Procedure 5   | internal function <code>brin_minmax_multi_options()</code>          |
| Support Procedure 11  | function to compute distance between two values (length of a range) |
| Operator Strategy 1   | operator less-than                                                  |
| Operator Strategy 2   | operator less-than-or-equal-to                                      |
| Operator Strategy 3   | operator equal-to                                                   |
| Operator Strategy 4   | operator greater-than-or-equal-to                                   |
| Operator Strategy 5   | operator greater-than                                               |

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in Table 65.6, or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported

operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

## 65.6. Hash Indexes

### 65.6.1. Overview

PostgreSQL includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the `=` operator, so `WHERE` clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for `SELECT` and `UPDATE`-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than `shared_buffers`/RAM.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's `LP_DEAD` bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during `VACUUM`.

If it can, `VACUUM` will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with `REINDEX`. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.

The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.

## 65.6.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is *\*no\** assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here, though are described in more detail in `src/backend/access/hash/README`. The split algorithm is crash safe and can be restarted if not completed successfully.

---

# Chapter 66. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

## 66.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as PGDATA (after the name of the environment variable that can be used to define it). A common location for PGDATA is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The PGDATA directory contains several subdirectories and control files, as shown in Table 66.1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in PGDATA, although it is possible to place them elsewhere.

**Table 66.1. Contents of PGDATA**

| Item             | Description                                                                      |
|------------------|----------------------------------------------------------------------------------|
| PG_VERSION       | A file containing the major version number of PostgreSQL                         |
| base             | Subdirectory containing per-database subdirectories                              |
| current_logfiles | File recording the log file(s) currently written to by the logging collector     |
| global           | Subdirectory containing cluster-wide tables, such as <code>pg_database</code>    |
| pg_commit_ts     | Subdirectory containing transaction commit timestamp data                        |
| pg_dynshmem      | Subdirectory containing files used by the dynamic shared memory subsystem        |
| pg_logical       | Subdirectory containing status data for logical decoding                         |
| pg_multixact     | Subdirectory containing multitransaction status data (used for shared row locks) |
| pg_notify        | Subdirectory containing LISTEN/NOTIFY status data                                |
| pg_repslot       | Subdirectory containing replication slot data                                    |
| pg_serial        | Subdirectory containing information about committed serializable transactions    |
| pg_snapshots     | Subdirectory containing exported snapshots                                       |
| pg_stat          | Subdirectory containing permanent files for the statistics subsystem             |
| pg_stat_tmp      | Subdirectory containing temporary files for the statistics subsystem             |
| pg_subtrans      | Subdirectory containing subtransaction status data                               |

| <code>postgresql.auto.conf</code> | A file used for storing configuration parameters that are set by <code>ALTER SYSTEM</code>                                                                                                                                                                                                                                                             |
| <code>postmaster.opts</code>      | A file recording the command-line options the server was last started with                                                                                                                                                                                                                                                                             |
| <code>postmaster.pid</code>       | A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (could be empty), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown) |

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin heap table access method, and the builtin index access methods. Due to the extensible nature of PostgreSQL, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where *BBB* is the process number of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see Section 66.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a *visibility map*, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in Section 66.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see Section 66.5).

### Caution

Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including `pg_class` itself, `pg_class.relfilenode` contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the `pg_relation_filenode()` function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named `filenode.1`, `filenode.2`, etc. This

arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option `--with-segsize` when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. `pg_class.relttoastrelid` links from a table to its TOAST table, if any. See Section 66.2 for more information.

The contents of tables and indexes are discussed further in Section 66.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP.NNN`, where `PPP` is the PID of the owning backend and `NNN` distinguishes different temporary files of that backend.

## 66.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 36.13.1 for more detail.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ( $2^{30} - 1$  bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

The compression technique used for either in-line or out-of-line compressed data can be selected for each column by setting the `COMPRESSION` column option in `CREATE TABLE` or `ALTER TABLE`. The default for columns with no explicit setting is to consult the `default_toast_compression` parameter at the time data is inserted.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code (in `access/common/toast_internals.c`) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 66.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 66.2.2.

## 66.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length), physical stored size (different if compression was applied), and the compression method used, if any. Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB, adjustable) or no more gains can be had. During an `UPDATE` operation, values of unchanged fields are normally preserved as-is; so an `UPDATE` of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage. This is the only possible strategy for columns of non-TOAST-able data types.
- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- **EXTERNAL** allows out-of-line storage but not compression. Use of **EXTERNAL** will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

`TOAST_TUPLE_TARGET` can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

## 66.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the *N*th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a

TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

## 66.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See `src/backend/storage/freespace/README` for more details on how the FSM is structured, and how it's updated and searched. The `pg_freespacemap` module can be used to examine the information stored in free space maps.

## 66.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The `pg_visibility` module can be used to examine the information stored in the visibility map.

## 66.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

## 66.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes.<sup>1</sup> Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 66.2 shows the overall layout of a page. There are five parts to each page.

**Table 66.2. Overall Page Layout**

| Item           | Description                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------|
| PageHeaderData | 24 bytes long. Contains general information about the page, including free space pointers.                       |
| ItemIdData     | Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item. |
| Free space     | The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.   |
| Items          | The actual items themselves.                                                                                     |
| Special space  | Index access method specific data. Different methods store different data. Empty in ordinary tables.             |

The first 24 bytes of each page consists of a page header (**PageHeaderData**). Its format is detailed in Table 66.3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if `-k` are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and

<sup>1</sup> Actually, use of this page format is not required for either table or index access methods. The heap table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

**Table 66.3. PageHeaderData Layout**

| Field               | Type           | Length  | Description                                                               |
|---------------------|----------------|---------|---------------------------------------------------------------------------|
| pd_lsn              | PageXLogRecPtr | 8 bytes | LSN: next byte after last byte of WAL record for last change to this page |
| pd_checksum         | uint16         | 2 bytes | Page checksum                                                             |
| pd_flags            | uint16         | 2 bytes | Flag bits                                                                 |
| pd_lower            | LocationIndex  | 2 bytes | Offset to start of free space                                             |
| pd_upper            | LocationIndex  | 2 bytes | Offset to end of free space                                               |
| pd_special          | LocationIndex  | 2 bytes | Offset to start of special space                                          |
| pd_pagesize_version | uint16         | 2 bytes | Page size and layout version number information                           |
| pd_prune_xid        | TransactionId  | 4 bytes | Oldest unpruned XMAX on page, or zero if none                             |

All the details can be found in `src/include/storage/bufpage.h`.

Following the page header are item identifiers (**ItemIdData**), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (**ItemPointer**, also known as **CTID**) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named **HeapTupleHeaderData**, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

Figure 66.1 illustrates how these parts are laid out in a page.

**Figure 66.1. Page Layout**

## 66.6.1. Table Row Layout

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 66.4. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in `t_infomask2`). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID_OLD` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

**Table 66.4. HeapTupleHeaderData Layout**

| Field                    | Type            | Length  | Description                                                         |
|--------------------------|-----------------|---------|---------------------------------------------------------------------|
| <code>t_xmin</code>      | TransactionId   | 4 bytes | insert XID stamp                                                    |
| <code>t_xmax</code>      | TransactionId   | 4 bytes | delete XID stamp                                                    |
| <code>t_cid</code>       | CommandId       | 4 bytes | insert and/or delete CID stamp (overlays with <code>t_xvac</code> ) |
| <code>t_xvac</code>      | TransactionId   | 4 bytes | XID for VACUUM operation moving a row version                       |
| <code>t_ctid</code>      | ItemPointerData | 6 bytes | current TID of this or newer row version                            |
| <code>t_infomask2</code> | uint16          | 2 bytes | number of attributes, plus various flag bits                        |
| <code>t_infomask</code>  | uint16          | 2 bytes | various flag bits                                                   |
| <code>t_hoff</code>      | uint8           | 1 byte  | offset to user data                                                 |

All the details can be found in `src/include/access/htup_details.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 66.2).

## 66.7. Heap-Only Tuples (HOT)

To allow for high concurrency, PostgreSQL uses multiversion concurrency control (MVCC) to store rows. However, MVCC has some downsides for update queries. Specifically, updates require new versions of rows to be added to tables. This can also require new index entries for each updated row, and removal of old versions of rows and their index entries can be expensive.

To help reduce the overhead of updates, PostgreSQL has an optimization called heap-only tuples (HOT). This optimization is possible when:

- The update does not modify any columns referenced by the table's indexes, not including summarizing indexes. The only summarizing index method in the core PostgreSQL distribution is BRIN.
- There is sufficient free space on the page containing the old row for the updated row.

In such cases, heap-only tuples provide two optimizations:

- New index entries are not needed to represent updated rows, however, summary indexes may still need to be updated.
- When a row is updated multiple times, row versions other than the oldest and the newest can be completely removed during normal operation, including `SELECTs`, instead of requiring periodic vacuum operations. (Indexes always refer to the page item identifier of the original row version. The tuple data associated with that row version is removed, and its item identifier is converted to a redirect that points to the oldest version that may still be visible to some concurrent transaction. Intermediate row versions that are no longer visible to anyone are completely removed, and the associated page item identifiers are made available for reuse.)

You can increase the likelihood of sufficient page space for HOT updates by decreasing a table's `fillfactor`. If you don't, HOT updates will still happen because new rows will naturally migrate to new pages and existing pages with sufficient free space for new row versions. The system view `pg_stat_all_tables` allows monitoring of the occurrence of HOT and non-HOT updates.

---

# Chapter 67. Transaction Processing

This chapter provides an overview of the internals of PostgreSQL's transaction management system. The word transaction is often abbreviated as *xact*.

## 67.1. Transactions and Identifiers

Transactions can be created explicitly using `BEGIN` or `START TRANSACTION` and ended using `COMMIT` or `ROLLBACK`. SQL statements outside of explicit transactions automatically use single-statement transactions.

Every transaction is identified by a unique `VirtualTransactionId` (also called `virtualXID` or `vxid`), which is comprised of a backend's process number (or `procNumber`) and a sequentially-assigned number local to each backend, known as `localXID`. For example, the virtual transaction ID 4/12532 has a `procNumber` of 4 and a `localXID` of 12532.

Non-virtual `TransactionIds` (or `xid`), e.g., 278394, are assigned sequentially to transactions from a global counter used by all databases within the PostgreSQL cluster. This assignment happens when a transaction first writes to the database. This means lower-numbered `xids` started writing before higher-numbered `xids`. Note that the order in which transactions perform their first database write might be different from the order in which the transactions started, particularly if the transaction started with statements that only performed database reads.

The internal transaction ID type `xid` is 32 bits wide and wraps around every 4 billion transactions. A 32-bit epoch is incremented during each wraparound. There is also a 64-bit type `xid8` which includes this epoch and therefore does not wrap around during the life of an installation; it can be converted to `xid` by casting. The functions in Table 9.84 return `xid8` values. `Xids` are used as the basis for PostgreSQL's MVCC concurrency mechanism and streaming replication.

When a top-level transaction with a (non-virtual) `xid` commits, it is marked as committed in the `pg_xact` directory. Additional information is recorded in the `pg_commit_ts` directory if `track_commit_timestamp` is enabled.

In addition to `vxid` and `xid`, prepared transactions are also assigned Global Transaction Identifiers (GID). GIDs are string literals up to 200 bytes long, which must be unique amongst other currently prepared transactions. The mapping of GID to `xid` is shown in `pg_prepared_xacts`.

## 67.2. Transactions and Locking

The transaction IDs of currently executing transactions are shown in `pg_locks` in columns `virtualxid` and `transactionid`. Read-only transactions will have `virtualxids` but NULL `transactionids`, while both columns will be set in read-write transactions.

Some lock types wait on `virtualxid`, while other types wait on `transactionid`. Row-level read and write locks are recorded directly in the locked rows and can be inspected using the `pgrowlocks` extension. Row-level read locks might also require the assignment of multixact IDs (`mxid`; see Section 24.1.5.1).

## 67.3. Subtransactions

Subtransactions are started inside transactions, allowing large transactions to be broken into smaller units. Subtransactions can commit or abort without affecting their parent transactions, allowing parent transactions to continue. This allows errors to be handled more easily, which is a common application development pattern. The word subtransaction is often abbreviated as *subxact*.

Subtransactions can be started explicitly using the `SAVEPOINT` command, but can also be started in other ways, such as PL/pgSQL's `EXCEPTION` clause. PL/Python and PL/Tcl also support explicit

subtransactions. Subtransactions can also be started from other subtransactions. The top-level transaction and its child subtransactions form a hierarchy or tree, which is why we refer to the main transaction as the top-level transaction.

If a subtransaction is assigned a non-virtual transaction ID, its transaction ID is referred to as a “subxid”. Read-only subtransactions are not assigned subxids, but once they attempt to write, they will be assigned one. This also causes all of a subxid's parents, up to and including the top-level transaction, to be assigned non-virtual transaction ids. We ensure that a parent xid is always lower than any of its child subxids.

The immediate parent xid of each subxid is recorded in the `pg_subtrans` directory. No entry is made for top-level xids since they do not have a parent, nor is an entry made for read-only subtransactions.

When a subtransaction commits, all of its committed child subtransactions with subxids will also be considered subcommitted in that transaction. When a subtransaction aborts, all of its child subtransactions will also be considered aborted.

When a top-level transaction with an xid commits, all of its subcommitted child subtransactions are also persistently recorded as committed in the `pg_xact` subdirectory. If the top-level transaction aborts, all its subtransactions are also aborted, even if they were subcommitted.

The more subtransactions each transaction keeps open (not rolled back or released), the greater the transaction management overhead. Up to 64 open subxids are cached in shared memory for each backend; after that point, the storage I/O overhead increases significantly due to additional lookups of subxid entries in `pg_subtrans`.

## 67.4. Two-Phase Transactions

PostgreSQL supports a two-phase commit (2PC) protocol that allows multiple distributed systems to work together in a transactional manner. The commands are `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED`. Two-phase transactions are intended for use by external transaction management systems. PostgreSQL follows the features and model proposed by the X/Open XA standard, but does not implement some less often used aspects.

When the user executes `PREPARE TRANSACTION`, the only possible next commands are `COMMIT PREPARED` or `ROLLBACK PREPARED`. In general, this prepared state is intended to be of very short duration, but external availability issues might mean transactions stay in this state for an extended interval. Short-lived prepared transactions are stored only in shared memory and WAL. Transactions that span checkpoints are recorded in the `pg_twophase` directory. Transactions that are currently prepared can be inspected using `pg_prepared_xacts`.

---

# Chapter 68. System Catalog Declarations and Initial Contents

PostgreSQL uses many different system catalogs to keep track of the existence and properties of database objects, such as tables and functions. Physically there is no difference between a system catalog and a plain user table, but the backend C code knows the structure and properties of each catalog, and can manipulate it directly at a low level. Thus, for example, it is inadvisable to attempt to alter the structure of a catalog on-the-fly; that would break assumptions built into the C code about how rows of the catalog are laid out. But the structure of the catalogs can change between major versions.

The structures of the catalogs are declared in specially formatted C header files in the `src/include/catalog/` directory of the source tree. For each catalog there is a header file named after the catalog (e.g., `pg_class.h` for `pg_class`), which defines the set of columns the catalog has, as well as some other basic properties such as its OID.

Many of the catalogs have initial data that must be loaded into them during the “bootstrap” phase of `initdb`, to bring the system up to a point where it is capable of executing SQL commands. (For example, `pg_class.h` must contain an entry for itself, as well as one for each other system catalog and index.) This initial data is kept in editable form in data files that are also stored in the `src/include/catalog/` directory. For example, `pg_proc.dat` describes all the initial rows that must be inserted into the `pg_proc` catalog.

To create the catalog files and load this initial data into them, a backend running in bootstrap mode reads a BKI (Backend Interface) file containing commands and initial data. The `postgres.bki` file used in this mode is prepared from the aforementioned header and data files, while building a PostgreSQL distribution, by a Perl script named `genbki.pl`. Although it's specific to a particular PostgreSQL release, `postgres.bki` is platform-independent and is installed in the `share` subdirectory of the installation tree.

`genbki.pl` also produces a derived header file for each catalog, for example `pg_class_d.h` for the `pg_class` catalog. This file contains automatically-generated macro definitions, and may contain other macros, enum declarations, and so on that can be useful for client C code that reads a particular catalog.

Most PostgreSQL developers don't need to be directly concerned with the BKI file, but almost any nontrivial feature addition in the backend will require modifying the catalog header files and/or initial data files. The rest of this chapter gives some information about that, and for completeness describes the BKI file format.

## 68.1. System Catalog Declaration Rules

The key part of a catalog header file is a C structure definition describing the layout of each row of the catalog. This begins with a `CATALOG` macro, which so far as the C compiler is concerned is just shorthand for `typedef struct FormData_catalogname`. Each field in the struct gives rise to a catalog column. Fields can be annotated using the BKI property macros described in `genbki.h`, for example to define a default value for a field or mark it as nullable or not nullable. The `CATALOG` line can also be annotated, with some other BKI property macros described in `genbki.h`, to define other properties of the catalog as a whole, such as whether it is a shared relation.

The system catalog cache code (and most catalog-munging code in general) assumes that the fixed-length portions of all system catalog tuples are in fact present, because it maps this C struct declaration onto them. Thus, all variable-length fields and nullable fields must be placed at the end, and they cannot be accessed as struct fields. For example, if you tried to set `pg_type.typeid` to be `NULL`, it would fail when some piece of code tried to reference `typetup->typeid` (or worse, `typetup->typelem`, because that follows `typeid`). This would result in random errors or even segmentation violations.

As a partial guard against this type of error, variable-length or nullable fields should not be made directly visible to the C compiler. This is accomplished by wrapping them in `#ifdef CATALOG_VARLEN ... #endif` (where `CATALOG_VARLEN` is a symbol that is never defined). This prevents C code from carelessly trying to access fields that might not be there or might be at some other offset. As an independent guard against creating incorrect rows, we require all columns that should be non-nullable to be marked so in `pg_attribute`. The bootstrap code will automatically mark catalog columns as `NOT NULL` if they are fixed-width and are not preceded by any nullable or variable-width column. Where this rule is inadequate, you can force correct marking by using `BKI_FORCE_NOT_NULL` and `BKI_FORCE_NULL` annotations as needed.

Frontend code should not include any `pg_xxx.h` catalog header file, as these files may contain C code that won't compile outside the backend. (Typically, that happens because these files also contain declarations for functions in `src/backend/catalog/` files.) Instead, frontend code may include the corresponding generated `pg_xxx_d.h` header, which will contain `OID #defines` and any other data that might be of use on the client side. If you want macros or other code in a catalog header to be visible to frontend code, write `#ifdef EXPOSE_TO_CLIENT_CODE ... #endif` around that section to instruct `genbki.pl` to copy that section to the `pg_xxx_d.h` header.

A few of the catalogs are so fundamental that they can't even be created by the `BKI create` command that's used for most catalogs, because that command needs to write information into these catalogs to describe the new catalog. These are called *bootstrap* catalogs, and defining one takes a lot of extra work: you have to manually prepare appropriate entries for them in the pre-loaded contents of `pg_class` and `pg_type`, and those entries will need to be updated for subsequent changes to the catalog's structure. (Bootstrap catalogs also need pre-loaded entries in `pg_attribute`, but fortunately `genbki.pl` handles that chore nowadays.) Avoid making new catalogs be bootstrap catalogs if at all possible.

## 68.2. System Catalog Initial Data

Each catalog that has any manually-created initial data (some do not) has a corresponding `.dat` file that contains its initial data in an editable format.

### 68.2.1. Data File Format

Each `.dat` file contains Perl data structure literals that are simply eval'd to produce an in-memory data structure consisting of an array of hash references, one per catalog row. A slightly modified excerpt from `pg_database.dat` will demonstrate the key features:

```
[
# A comment could appear here.
{ oid => '1', oid_symbol => 'Template1DbOid',
  descr => 'database\'s default template',
  datname => 'template1', encoding => 'ENCODING',
  datlocprovider => 'LOCALE_PROVIDER', datistemplate => 't',
  datallowconn => 't', dathasloginevt => 'f', datconnlimit => '-1',
  datfrozenxid => '0',
  datminmxid => '1', dattablespace => 'pg_default', datcollate =>
  'LC_COLLATE',
  datctype => 'LC_CTYPE', datlocale => 'DATLOCALE', datacl =>
  '_null_' },
]
```

Points to note:

- The overall file layout is: open square bracket, one or more sets of curly braces each of which represents a catalog row, close square bracket. Write a comma after each closing curly brace.

- Within each catalog row, write comma-separated *key => value* pairs. The allowed *keys* are the names of the catalog's columns, plus the metadata keys `oid`, `oid_symbol`, `array_type_oid`, and `descr`. (The use of `oid` and `oid_symbol` is described in Section 68.2.2 below, while `array_type_oid` is described in Section 68.2.4. `descr` supplies a description string for the object, which will be inserted into `pg_description` or `pg_shdescription` as appropriate.) While the metadata keys are optional, the catalog's defined columns must all be provided, except when the catalog's `.h` file specifies a default value for the column. (In the example above, the `datdba` field has been omitted because `pg_database.h` supplies a suitable default value for it.)
- All values must be single-quoted. Escape single quotes used within a value with a backslash. Backslashes meant as data can, but need not, be doubled; this follows Perl's rules for simple quoted literals. Note that backslashes appearing as data will be treated as escapes by the bootstrap scanner, according to the same rules as for escape string constants (see Section 4.1.2.2); for example `\t` converts to a tab character. If you actually want a backslash in the final value, you will need to write four of them: Perl strips two, leaving `\\` for the bootstrap scanner to see.
- Null values are represented by `_null_`. (Note that there is no way to create a value that is just that string.)
- Comments are preceded by `#`, and must be on their own lines.
- Field values that are OIDs of other catalog entries should be represented by symbolic names rather than actual numeric OIDs. (In the example above, `dat_tablespace` contains such a reference.) This is described in Section 68.2.3 below.
- Since hashes are unordered data structures, field order and line layout aren't semantically significant. However, to maintain a consistent appearance, we set a few rules that are applied by the formatting script `reformat_dat_file.pl`:
  - Within each pair of curly braces, the metadata fields `oid`, `oid_symbol`, `array_type_oid`, and `descr` (if present) come first, in that order, then the catalog's own fields appear in their defined order.
  - Newlines are inserted between fields as needed to limit line length to 80 characters, if possible. A newline is also inserted between the metadata fields and the regular fields.
  - If the catalog's `.h` file specifies a default value for a column, and a data entry has that same value, `reformat_dat_file.pl` will omit it from the data file. This keeps the data representation compact.
  - `reformat_dat_file.pl` preserves blank lines and comment lines as-is.
- It's recommended to run `reformat_dat_file.pl` before submitting catalog data patches. For convenience, you can simply change to `src/include/catalog/` and run `make reformat-dat-files`.
- If you want to add a new method of making the data representation smaller, you must implement it in `reformat_dat_file.pl` and also teach `Catalog::ParseData()` how to expand the data back into the full representation.

## 68.2.2. OID Assignment

A catalog row appearing in the initial data can be given a manually-assigned OID by writing an `oid => nnnn` metadata field. Furthermore, if an OID is assigned, a C macro for that OID can be created by writing an `oid_symbol => name` metadata field.

Pre-loaded catalog rows must have preassigned OIDs if there are OID references to them in other pre-loaded rows. A preassigned OID is also needed if the row's OID must be referenced from C code. If neither case applies, the `oid` metadata field can be omitted, in which case the bootstrap code assigns an OID automatically. In practice we usually preassign OIDs for all or none of the pre-loaded rows in a given catalog, even if only some of them are actually cross-referenced.

Writing the actual numeric value of any OID in C code is considered very bad form; always use a macro, instead. Direct references to `pg_proc` OIDs are common enough that there's a special mechanism to create the necessary macros automatically; see `src/backend/utils/Gen_fm-grtab.pl`. Similarly — but, for historical reasons, not done the same way — there's an automatic method for creating macros for `pg_type` OIDs. `oid_symbol` entries are therefore not necessary in those two catalogs. Likewise, macros for the `pg_class` OIDs of system catalogs and indexes are set up automatically. For all other system catalogs, you have to manually specify any macros you need via `oid_symbol` entries.

To find an available OID for a new pre-loaded row, run the script `src/include/catalog/unused_oids`. It prints inclusive ranges of unused OIDs (e.g., the output line `45-900` means OIDs 45 through 900 have not been allocated yet). Currently, OIDs 1–9999 are reserved for manual assignment; the `unused_oids` script simply looks through the catalog headers and `.dat` files to see which ones do not appear. You can also use the `duplicate_oids` script to check for mistakes. (`genbki.pl` will assign OIDs for any rows that didn't get one hand-assigned to them, and it will also detect duplicate OIDs at compile time.)

When choosing OIDs for a patch that is not expected to be committed immediately, best practice is to use a group of more-or-less consecutive OIDs starting with some random choice in the range 8000—9999. This minimizes the risk of OID collisions with other patches being developed concurrently. To keep the 8000—9999 range free for development purposes, after a patch has been committed to the master git repository its OIDs should be renumbered into available space below that range. Typically, this will be done near the end of each development cycle, moving all OIDs consumed by patches committed in that cycle at the same time. The script `renumber_oids.pl` can be used for this purpose. If an uncommitted patch is found to have OID conflicts with some recently-committed patch, `renumber_oids.pl` may also be useful for recovering from that situation.

Because of this convention of possibly renumbering OIDs assigned by patches, the OIDs assigned by a patch should not be considered stable until the patch has been included in an official release. We do not change manually-assigned object OIDs once released, however, as that would create assorted compatibility problems.

If `genbki.pl` needs to assign an OID to a catalog entry that does not have a manually-assigned OID, it will use a value in the range 10000—11999. The server's OID counter is set to 10000 at the start of a bootstrap run, so that any objects created on-the-fly during bootstrap processing also receive OIDs in this range. (The usual OID assignment mechanism takes care of preventing any conflicts.)

Objects with OIDs below `FirstUnpinnedObjectId` (12000) are considered “pinned”, preventing them from being deleted. (There are a small number of exceptions, which are hard-wired into `ISpinnedObject()`.) `initdb` forces the OID counter up to `FirstUnpinnedObjectId` as soon as it's ready to create unpinned objects. Thus objects created during the later phases of `initdb`, such as objects created while running the `information_schema.sql` script, will not be pinned, while all objects known to `genbki.pl` will be.

OIDs assigned during normal database operation are constrained to be 16384 or higher. This ensures that the range 10000—16383 is free for OIDs assigned automatically by `genbki.pl` or during `initdb`. These automatically-assigned OIDs are not considered stable, and may change from one installation to another.

## 68.2.3. OID Reference Lookup

In principle, cross-references from one initial catalog row to another could be written just by writing the preassigned OID of the referenced row in the referencing field. However, that is against project policy, because it is error-prone, hard to read, and subject to breakage if a newly-assigned OID is renumbered. Therefore `genbki.pl` provides mechanisms to write symbolic references instead. The rules are as follows:

- Use of symbolic references is enabled in a particular catalog column by attaching `BKI_LOOKUP(lookuprule)` to the column's definition, where *lookuprule* is the name of

the referenced catalog, e.g., `pg_proc`. `BKI_LOOKUP` can be attached to columns of type `Oid`, `regproc`, `oidvector`, or `Oid[ ]`; in the latter two cases it implies performing a lookup on each element of the array.

- It's also permissible to attach `BKI_LOOKUP(encoding)` to integer columns to reference character set encodings, which are not currently represented as catalog OIDs, but have a set of values known to `genbki.pl`.
- In some catalog columns, it's allowed for entries to be zero instead of a valid reference. If this is allowed, write `BKI_LOOKUP_OPT` instead of `BKI_LOOKUP`. Then you can write `0` for an entry. (If the column is declared `regproc`, you can optionally write `-` instead of `0`.) Except for this special case, all entries in a `BKI_LOOKUP` column must be symbolic references. `genbki.pl` will warn about unrecognized names.
- Most kinds of catalog objects are simply referenced by their names. Note that type names must exactly match the referenced `pg_type` entry's `typname`; you do not get to use any aliases such as `integer` for `int4`.
- A function can be represented by its `prname`, if that is unique among the `pg_proc.dat` entries (this works like `regproc` input). Otherwise, write it as `prname(argtypename, argtype-name, ...)`, like `regprocedure`. The argument type names must be spelled exactly as they are in the `pg_proc.dat` entry's `proargtypes` field. Do not insert any spaces.
- Operators are represented by `oprname(lefttype, righttype)`, writing the type names exactly as they appear in the `pg_operator.dat` entry's `oprleft` and `oprright` fields. (Write `0` for the omitted operand of a unary operator.)
- The names of `opclasses` and `opfamilies` are only unique within an access method, so they are represented by `access_method_name/object_name`.
- In none of these cases is there any provision for schema-qualification; all objects created during bootstrap are expected to be in the `pg_catalog` schema.

`genbki.pl` resolves all symbolic references while it runs, and puts simple numeric OIDs into the emitted BKI file. There is therefore no need for the bootstrap backend to deal with symbolic references.

It's desirable to mark OID reference columns with `BKI_LOOKUP` or `BKI_LOOKUP_OPT` even if the catalog has no initial data that requires lookup. This allows `genbki.pl` to record the foreign key relationships that exist in the system catalogs. That information is used in the regression tests to check for incorrect entries. See also the macros `DECLARE_FOREIGN_KEY`, `DECLARE_FOREIGN_KEY_OPT`, `DECLARE_ARRAY_FOREIGN_KEY`, and `DECLARE_ARRAY_FOREIGN_KEY_OPT`, which are used to declare foreign key relationships that are too complex for `BKI_LOOKUP` (typically, multi-column foreign keys).

## 68.2.4. Automatic Creation of Array Types

Most scalar data types should have a corresponding array type (that is, a standard varlena array type whose element type is the scalar type, and which is referenced by the `typarray` field of the scalar type's `pg_type` entry). `genbki.pl` is able to generate the `pg_type` entry for the array type automatically in most cases.

To use this facility, just write an `array_type_oid => nnnn` metadata field in the scalar type's `pg_type` entry, specifying the OID to use for the array type. You may then omit the `typarray` field, since it will be filled automatically with that OID.

The generated array type's name is the scalar type's name with an underscore prepended. The array entry's other fields are filled from `BKI_ARRAY_DEFAULT(value)` annotations in `pg_type.h`, or if there isn't one, copied from the scalar type. (There's also a special case for `typalign`.) Then the `typelem` and `typarray` fields of the two entries are set to cross-reference each other.

## 68.2.5. Recipes for Editing Data Files

Here are some suggestions about the easiest ways to perform common tasks when updating catalog data files.

**Add a new column with a default to a catalog:** Add the column to the header file with a `BKI_DEFAULT(value)` annotation. The data file need only be adjusted by adding the field in existing rows where a non-default value is needed.

**Add a default value to an existing column that doesn't have one:** Add a `BKI_DEFAULT` annotation to the header file, then run `make reformat-dat-files` to remove now-redundant field entries.

**Remove a column, whether it has a default or not:** Remove the column from the header, then run `make reformat-dat-files` to remove now-useless field entries.

**Change or remove an existing default value:** You cannot simply change the header file, since that will cause the current data to be interpreted incorrectly. First run `make expand-dat-files` to rewrite the data files with all default values inserted explicitly, then change or remove the `BKI_DEFAULT` annotation, then run `make reformat-dat-files` to remove superfluous fields again.

**Ad-hoc bulk editing:** `reformat_dat_file.pl` can be adapted to perform many kinds of bulk changes. Look for its block comments showing where one-off code can be inserted. In the following example, we are going to consolidate two Boolean fields in `pg_proc` into a char field:

1. Add the new column, with a default, to `pg_proc.h`:

```
+ /* see PROKIND_ categories below */
+ char          prokind BKI_DEFAULT(f);
```

2. Create a new script based on `reformat_dat_file.pl` to insert appropriate values on-the-fly:

```
-          # At this point we have the full row in memory as a
hash
-          # and can do any operations we want. As written, it
only
-          # removes default values, but this script can be
adapted to
-          # do one-off bulk-editing.
+          # One-off change to migrate to prokind
+          # Default has already been filled in by now, so
change to other
+          # values as appropriate
+          if ($values{proisagg} eq 't')
+          {
+              $values{prokind} = 'a';
+          }
+          elsif ($values{proiswindow} eq 't')
+          {
+              $values{prokind} = 'w';
+          }
```

3. Run the new script:

```
$ cd src/include/catalog
$ perl rewrite_dat_with_prokind.pl pg_proc.dat
```

At this point `pg_proc.dat` has all three columns, `prokind`, `proisagg`, and `proiswindow`, though they will appear only in rows where they have non-default values.

4. Remove the old columns from `pg_proc.h`:

```
-    /* is it an aggregate? */
-    bool        proisagg BKI_DEFAULT(f);
-
-    /* is it a window function? */
-    bool        proiswindow BKI_DEFAULT(f);
```

5. Finally, run `make reformat-dat-files` to remove the useless old entries from `pg_proc.dat`.

For further examples of scripts used for bulk editing, see `convert_oid2name.pl` and `remove_pg_type_oid_symbols.pl` attached to this message: <https://www.postgresql.org/message-id/CAJVSVGX8gXnPm+Xa=DxR7kFYprcQ1tNcCT5D0O3ShfnM6jehA@mail.gmail.com>

## 68.3. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the `postgres.bki` file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), identifiers, numbers, or single-quoted strings. Everything is case sensitive.

Lines starting with `#` are ignored.

## 68.4. BKI Commands

```
create tablename tableoid [bootstrap] [shared_relation] [rowtype_oid oid]
(name1 = type1 [FORCE NOT NULL | FORCE NULL] [, name2 = type2 [FORCE NOT NULL
| FORCE NULL ], ...)
```

Create a table named *tablename*, and having the OID *tableoid*, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: `bool`, `bytea`, `char` (1 byte), `name`, `int2`, `int4`, `regproc`, `regclass`, `regtype`, `text`, `oid`, `tid`, `xid`, `cid`, `int2vector`, `oidvector`, `_int4` (array), `_text` (array), `_oid` (array), `_char` (array), `_aclitem` (array). Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrap catalogs, but non-bootstrap catalogs can contain any built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into `pg_class`, `pg_attribute`, etc., for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with `insert` commands). This option is used for creating `pg_class` etc. themselves.

The table is created as shared if `shared_relation` is specified. The table's row type OID (`pg_type` OID) can optionally be specified via the `rowtype_oid` clause; if not specified, an

OID is automatically generated for it. (The `rowtype_oid` clause is useless if `bootstrap` is specified, but it can be provided anyway for documentation.)

`open tablename`

Open the table named *tablename* for insertion of data. Any currently open table is closed.

`close tablename`

Close the open table. The name of the table must be given as a cross-check.

`insert ( [oid_value] value1 value2 ... )`

Insert a new row into the open table using *value1*, *value2*, etc., for its column values.

NULL values can be specified using the special key word `_null_`. Values that do not look like identifiers or digit strings must be single-quoted. (To include a single quote in a value, write it twice. Escape-string-style backslash escapes are allowed in the string, too.)

`declare [unique] index indexname indexoid on tablename using amname ( op-class1 name1 [, ...] )`

Create an index named *indexname*, having OID *indexoid*, on the table named *tablename*, using the *amname* access method. The fields to index are called *name1*, *name2* etc., and the operator classes to use are *opclass1*, *opclass2* etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

`declare toast toasttableoid toastindexoid on tablename`

Create a TOAST table for the table named *tablename*. The TOAST table is assigned OID *toasttableoid* and its index is assigned OID *toastindexoid*. As with `declare index`, filling of the index is postponed.

`build indices`

Fill in the indices that have previously been declared.

## 68.5. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow those tables themselves to be filled, `create` with the `bootstrap` option implicitly opens the created table for data insertion.

Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap` one of the critical tables
2. `insert` data describing at least the critical tables
3. `close`
4. Repeat for the other critical tables.
5. `create` (without `bootstrap`) a noncritical table
6. `open`

7. `insert` desired data
8. `close`
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. `build indices`

There are doubtless other, undocumented ordering dependencies.

## 68.6. BKI Example

The following sequence of commands will create the table `test_table` with OID 420, having three columns `oid`, `cola` and `colb` of type `oid`, `int4` and `text`, respectively, and insert two rows into the table:

```
create test_table 420 (oid = oid, cola = int4, colb = text)
open test_table
insert ( 421 1 'value 1' )
insert ( 422 2 _null_ )
close test_table
```

---

# Chapter 69. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

## 69.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples  
-----+-----  
    358 |    10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

QUERY PLAN

```
-----  
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007  
width=244)  
  Recheck Cond: (unique1 < 1000)  
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80  
        rows=1007 width=0)
```

Index Cond: (unique1 < 1000)

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarlt_sel`. The `scalarlt_sel` function retrieves the histogram for `unique1` from `pg_statistic`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';
```

                  histogram\_bounds

-----  
{0, 993, 1997, 3050, 4040, 5036, 5957, 7057, 8029, 9016, 9995}

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max -
                bucket[2].min))/num_buckets
              = (1 + (1000 - 993)/(1997 - 993))/10
              = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

                  QUERY PLAN

-----  
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)  
  Filter: (stringu1 = 'CRAAAA'::name)

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs
FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac          | 0
n_distinct         | 676
most_common_vals   | {EJAAAA, BBAAAA, CRAAAA, FCAAAA, FEAAAA, GSAAAA,
JOAAAA, MCAAAA, NAAAAA, WGAAAA}
```

```
most_common_freqs | {0.00333333,0.003,0.003,0.003,0.003,0.003,
0.003,0.003,0.003,0.003}
```

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
             = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
      = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mcv_freqs))/(num_distinct - num_mcv)
             = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 +
0.003 +
                    0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
             = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
      = 15 (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

QUERY PLAN

```
-----  
Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)  
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for stringu1, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats  
WHERE tablename='tenk1' AND attname='stringu1';
```

histogram\_bounds

```
-----  
{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA,  
XLAAAA, ZAAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)  
             = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003  
             = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity *  
             histogram_fraction  
             = 0.01833333 + 0.298387 * 0.96966667  
             = 0.307669  
  
rows        = 10000 * 0.307669  
             = 3077 (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 =  
  'xxx';
```

QUERY PLAN

```
-----  
-----
```

```
Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
  -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80
rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 =
'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466

rows          = 10000 * 0.0001466
              = 1 (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

#### QUERY PLAN

```
-----
Nested Loop (cost=4.64..456.23 rows=50 width=488)
  -> Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50
width=244)
    Recheck Cond: (unique1 < 50)
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63
rows=50 width=0)
      Index Cond: (unique1 < 50)
  -> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27
rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)
```

The restriction on `tenk1, unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max -
bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035

rows          = 10000 * 0.005035
              = 50 (rounding off)
```

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```
SELECT tablename, null_frac, n_distinct, most_common_vals FROM
pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

| tablename | null_frac | n_distinct | most_common_vals |
|-----------|-----------|------------|------------------|
| tenk1     | 0         | -1         |                  |
| tenk2     | 0         | -1         |                  |

In this case there is no MCV information for `unique2` and all the values appear to be unique (`n_distinct = -1`), so we use an algorithm that relies on the row count estimates for both relations (`num_rows`, not shown, but "tenk") together with the column null fractions (zero for both):

```
selectivity = (1 - null_frac1) * (1 - null_frac2) / max(num_rows1,
num_rows2)
             = (1 - 0) * (1 - 0) / max(10000, 10000)
             = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the row count of the larger relation (this value does get scaled in the non-unique case). The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50
```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from `50 * 1`, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any `WHERE` clauses) is done in `src/backend/optimizer/util/plancat.c`. The generic logic for clause selectivities is in `src/backend/optimizer/path/clausesel.c`. The operator-specific selectivity functions are mostly found in `src/backend/utils/adt/selfuncs.c`.

## 69.2. Multivariate Statistics Examples

### 69.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1,
10000) s(i);
```

```
ANALYZE t;
```

As explained in Section 14.2, the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';
```

```
relpages | reltuples
-----+-----
      45 |      10000
```

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a `WHERE` condition on the `a` column:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a
= 1;
```

QUERY PLAN

```
-----
Seq Scan on t (cost=0.00..170.00 rows=100 width=8) (actual
rows=100.00 loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the `WHERE` condition to use the `b` column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with `AND`:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a
= 1 AND b = 1;
```

QUERY PLAN

```
-----
Seq Scan on t (cost=0.00..195.00 rows=1 width=8) (actual
rows=100.00 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs `ANALYZE` to calculate functional-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a
= 1 AND b = 1;
```

QUERY PLAN

```
-----  
-----  
Seq Scan on t (cost=0.00..195.00 rows=100 width=8) (actual  
rows=100.00 loops=1)  
  Filter: ((a = 1) AND (b = 1))  
  Rows Removed by Filter: 9900
```

## 69.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a `GROUP BY` clause. When `GROUP BY` lists a single column, the n-distinct estimate (which is visible as the estimated number of rows returned by the `HashAggregate` node) is very accurate:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT COUNT(*) FROM t  
GROUP BY a;
```

QUERY PLAN

```
-----  
-----  
HashAggregate (cost=195.00..196.00 rows=100 width=12) (actual  
rows=100.00 loops=1)  
  Group Key: a  
    -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=4)  
      (actual rows=10000.00 loops=1)
```

But without multivariate statistics, the estimate for the number of groups in a query with two columns in `GROUP BY`, as in the following example, is off by an order of magnitude:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT COUNT(*) FROM t  
GROUP BY a, b;
```

QUERY PLAN

```
-----  
-----  
HashAggregate (cost=220.00..230.00 rows=1000 width=16) (actual  
rows=100.00 loops=1)  
  Group Key: a, b  
    -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=8)  
      (actual rows=10000.00 loops=1)
```

By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```
DROP STATISTICS stts;  
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;  
ANALYZE t;  
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT COUNT(*) FROM t  
GROUP BY a, b;
```

QUERY PLAN

```
-----  
-----  
HashAggregate (cost=220.00..221.00 rows=100 width=16) (actual  
rows=100.00 loops=1)  
  Group Key: a, b  
    -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=8)  
      (actual rows=10000.00 loops=1)
```

### 69.2.3. MCV Lists

As explained in Section 69.2.1, functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in Section 69.1. These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in ANALYZE, storage and planning time.

Let's look at the query from Section 69.2.1 again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

```
DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a
= 1 AND b = 1;
```

#### QUERY PLAN

```
-----
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual
rows=100.00 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using `pg_mcv_list_items` set-returning function.

```
SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid
= stxoid),
```

```
pg_mcv_list_items(stxdmcv) m WHERE stxname =
```

```
'stts2';
```

| index | values   | nulls  | frequency | base_frequency |
|-------|----------|--------|-----------|----------------|
| 0     | {0, 0}   | {f, f} | 0.01      | 0.0001         |
| 1     | {1, 1}   | {f, f} | 0.01      | 0.0001         |
| ...   |          |        |           |                |
| 49    | {49, 49} | {f, f} | 0.01      | 0.0001         |
| 50    | {50, 50} | {f, f} | 0.01      | 0.0001         |
| ...   |          |        |           |                |
| 97    | {97, 97} | {f, f} | 0.01      | 0.0001         |
| 98    | {98, 98} | {f, f} | 0.01      | 0.0001         |
| 99    | {99, 99} | {f, f} | 0.01      | 0.0001         |

```
(100 rows)
```

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the `nulls` column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones. See `mcv_clauselist_selectivity` in `src/backend/statistics/mcv.c` for details.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a
= 1 AND b = 10;
```

QUERY PLAN

```
-----
Seq Scan on t (cost=0.00..195.00 rows=1 width=8) (actual
rows=0.00 loops=1)
  Filter: ((a = 1) AND (b = 10))
  Rows Removed by Filter: 10000
```

Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a
<= 49 AND b > 49;
```

QUERY PLAN

```
-----
Seq Scan on t (cost=0.00..195.00 rows=1 width=8) (actual
rows=0.00 loops=1)
  Filter: ((a <= 49) AND (b > 49))
  Rows Removed by Filter: 10000
```

## 69.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions. The `psql` program's `\do+` meta-command is useful to determine which operators are marked as leakproof.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leakproof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.

---

# Chapter 70. Backup Manifest Format

The backup manifest generated by `pg_basebackup` is primarily intended to permit the backup to be verified using `pg_verifybackup`. However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, PostgreSQL permits the `json` and `jsonb` data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

## 70.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

### `PostgreSQL-Backup-Manifest-Version`

The associated value is an integer. Beginning in PostgreSQL 17, it is 2; in older versions, it is 1.

### `System-Identifier`

The database system identifier of the PostgreSQL instance where the backup was taken. This field is present only when `PostgreSQL-Backup-Manifest-Version` is 2.

### `Files`

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in Section 70.2.

### `WAL-Ranges`

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in Section 70.3.

### `Manifest-Checksum`

This key is always present on the last line of the backup manifest file. The associated value is a SHA-256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA-256 checksum is significantly more expensive than a CRC-32C checksum, the manifest should normally be small enough that the extra computation won't matter very much.

## 70.2. Backup Manifest File Object

The object which describes a single file contains either a `Path` key or an `Encoded-Path` key. Normally, the `Path` key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablespace will have paths whose first two components are `pg_tblspc` and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the `Encoded-Path` key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

**Size**

The expected size of this file, as an integer.

**Last-Modified**

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by `pg_verifybackup`. It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

**Checksum-Algorithm**

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are CRC32C, SHA224, SHA256, SHA384, and SHA512.

**Checksum**

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

## 70.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

**Timeline**

The timeline for this range of WAL records, as an integer.

**Start-LSN**

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by PostgreSQL; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

**End-LSN**

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as **Start-LSN**.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

| F.2.1. Configuration Parameters .....                                 | 2804 |
| F.2.2. Author .....                                                   | 2804 |
| F.3. auto_explain — log execution plans of slow queries .....         | 2805 |
| F.3.1. Configuration Parameters .....                                 | 2805 |
| F.3.2. Example .....                                                  | 2807 |
| F.3.3. Author .....                                                   | 2807 |
| F.4. basebackup_to_shell — example "shell" pg_basebackup module ..... | 2808 |
| F.4.1. Configuration Parameters .....                                 | 2808 |
| F.4.2. Author .....                                                   | 2808 |
| F.5. basic_archive — an example WAL archive module .....              | 2809 |
| F.5.1. Configuration Parameters .....                                 | 2809 |
| F.5.2. Notes .....                                                    | 2809 |
| F.5.3. Author .....                                                   | 2809 |

|                                                                         |      |
|-------------------------------------------------------------------------|------|
| F.6. bloom — bloom filter index access method .....                     | 2810 |
| F.6.1. Parameters .....                                                 | 2810 |
| F.6.2. Examples .....                                                   | 2810 |
| F.6.3. Operator Class Interface .....                                   | 2813 |
| F.6.4. Limitations .....                                                | 2813 |
| F.6.5. Authors .....                                                    | 2813 |
| F.7. btree_gin — GIN operator classes with B-tree behavior .....        | 2814 |
| F.7.1. Example Usage .....                                              | 2814 |
| F.7.2. Authors .....                                                    | 2814 |
| F.8. btree_gist — GiST operator classes with B-tree behavior .....      | 2815 |
| F.8.1. Example Usage .....                                              | 2815 |
| F.8.2. Authors .....                                                    | 2816 |
| F.9. citext — a case-insensitive character string type .....            | 2817 |
| F.9.1. Rationale .....                                                  | 2817 |
| F.9.2. How to Use It .....                                              | 2817 |
| F.9.3. String Comparison Behavior .....                                 | 2818 |
| F.9.4. Limitations .....                                                | 2818 |
| F.9.5. Author .....                                                     | 2819 |
| F.10. cube — a multi-dimensional cube data type .....                   | 2820 |
| F.10.1. Syntax .....                                                    | 2820 |
| F.10.2. Precision .....                                                 | 2820 |
| F.10.3. Usage .....                                                     | 2820 |
| F.10.4. Defaults .....                                                  | 2823 |
| F.10.5. Notes .....                                                     | 2824 |
| F.10.6. Credits .....                                                   | 2824 |
| F.11. dblink — connect to other PostgreSQL databases .....              | 2825 |
| F.12. dict_int — example full-text search dictionary for integers ..... | 2857 |
| F.12.1. Configuration .....                                             | 2857 |
| F.12.2. Usage .....                                                     | 2857 |
| F.13. dict_xsyn — example synonym full-text search dictionary .....     | 2858 |
| F.13.1. Configuration .....                                             | 2858 |
| F.13.2. Usage .....                                                     | 2858 |
| F.14. earthdistance — calculate great-circle distances .....            | 2860 |
| F.14.1. Cube-Based Earth Distances .....                                | 2860 |
| F.14.2. Point-Based Earth Distances .....                               | 2861 |
| F.15. file_fdw — access data files in the server's file system .....    | 2862 |
| F.16. fuzzystrmatch — determine string similarities and distance .....  | 2865 |
| F.16.1. Soundex .....                                                   | 2865 |
| F.16.2. Daitch-Mokotoff Soundex .....                                   | 2866 |
| F.16.3. Levenshtein .....                                               | 2867 |
| F.16.4. Metaphone .....                                                 | 2868 |
| F.16.5. Double Metaphone .....                                          | 2869 |
| F.17. hstore — hstore key/value datatype .....                          | 2870 |
| F.17.1. hstore External Representation .....                            | 2870 |
| F.17.2. hstore Operators and Functions .....                            | 2870 |
| F.17.3. Indexes .....                                                   | 2874 |
| F.17.4. Examples .....                                                  | 2875 |
| F.17.5. Statistics .....                                                | 2876 |
| F.17.6. Compatibility .....                                             | 2877 |
| F.17.7. Transforms .....                                                | 2877 |
| F.17.8. Authors .....                                                   | 2877 |
| F.18. intagg — integer aggregator and enumerator .....                  | 2878 |
| F.18.1. Functions .....                                                 | 2878 |
| F.18.2. Sample Uses .....                                               | 2878 |
| F.19. intarray — manipulate arrays of integers .....                    | 2880 |
| F.19.1. intarray Functions and Operators .....                          | 2880 |
| F.19.2. Index Support .....                                             | 2882 |
| F.19.3. Example .....                                                   | 2882 |

|                                                                                        |      |
|----------------------------------------------------------------------------------------|------|
| F.19.4. Benchmark .....                                                                | 2882 |
| F.19.5. Authors .....                                                                  | 2883 |
| F.20. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.) ..... | 2884 |
| F.20.1. Data Types .....                                                               | 2884 |
| F.20.2. Casts .....                                                                    | 2885 |
| F.20.3. Functions and Operators .....                                                  | 2885 |
| F.20.4. Configuration Parameters .....                                                 | 2886 |
| F.20.5. Examples .....                                                                 | 2886 |
| F.20.6. Bibliography .....                                                             | 2887 |
| F.20.7. Author .....                                                                   | 2887 |
| F.21. lo — manage large objects .....                                                  | 2888 |
| F.21.1. Rationale .....                                                                | 2888 |
| F.21.2. How to Use It .....                                                            | 2888 |
| F.21.3. Limitations .....                                                              | 2888 |
| F.21.4. Author .....                                                                   | 2889 |
| F.22. ltree — hierarchical tree-like data type .....                                   | 2890 |
| F.22.1. Definitions .....                                                              | 2890 |
| F.22.2. Operators and Functions .....                                                  | 2891 |
| F.22.3. Indexes .....                                                                  | 2893 |
| F.22.4. Example .....                                                                  | 2894 |
| F.22.5. Transforms .....                                                               | 2896 |
| F.22.6. Authors .....                                                                  | 2896 |
| F.23. pageinspect — low-level inspection of database pages .....                       | 2897 |
| F.23.1. General Functions .....                                                        | 2897 |
| F.23.2. Heap Functions .....                                                           | 2898 |
| F.23.3. B-Tree Functions .....                                                         | 2899 |
| F.23.4. BRIN Functions .....                                                           | 2902 |
| F.23.5. GIN Functions .....                                                            | 2903 |
| F.23.6. GiST Functions .....                                                           | 2904 |
| F.23.7. Hash Functions .....                                                           | 2906 |
| F.24. passwordcheck — verify password strength .....                                   | 2908 |
| F.24.1. Configuration Parameters .....                                                 | 2908 |
| F.25. pg_buffercache — inspect PostgreSQL buffer cache state .....                     | 2909 |
| F.25.1. The pg_buffercache View .....                                                  | 2909 |
| F.25.2. The pg_buffercache_numa View .....                                             | 2910 |
| F.25.3. The pg_buffercache_summary() Function .....                                    | 2910 |
| F.25.4. The pg_buffercache_usage_counts() Function .....                               | 2911 |
| F.25.5. The pg_buffercache_evict() Function .....                                      | 2911 |
| F.25.6. The pg_buffercache_evict_relation() Function .....                             | 2912 |
| F.25.7. The pg_buffercache_evict_all() Function .....                                  | 2912 |
| F.25.8. Sample Output .....                                                            | 2912 |
| F.25.9. Authors .....                                                                  | 2913 |
| F.26. pgcrypto — cryptographic functions .....                                         | 2914 |
| F.26.1. General Hashing Functions .....                                                | 2914 |
| F.26.2. Password Hashing Functions .....                                               | 2914 |
| F.26.3. PGP Encryption Functions .....                                                 | 2917 |
| F.26.4. Raw Encryption Functions .....                                                 | 2922 |
| F.26.5. Random-Data Functions .....                                                    | 2923 |
| F.26.6. OpenSSL Support Functions .....                                                | 2923 |
| F.26.7. Configuration Parameters .....                                                 | 2923 |
| F.26.8. Notes .....                                                                    | 2923 |
| F.26.9. Author .....                                                                   | 2924 |
| F.27. pg_freespacemap — examine the free space map .....                               | 2925 |
| F.27.1. Functions .....                                                                | 2925 |
| F.27.2. Sample Output .....                                                            | 2925 |
| F.27.3. Author .....                                                                   | 2926 |
| F.28. pg_logicalinspect — logical decoding components inspection .....                 | 2927 |
| F.28.1. Functions .....                                                                | 2927 |

|                                                                                              |      |
|----------------------------------------------------------------------------------------------|------|
| F.28.2. Author .....                                                                         | 2928 |
| F.29. <code>pg_overexplain</code> — allow EXPLAIN to dump even more details .....            | 2929 |
| F.29.1. EXPLAIN (DEBUG) .....                                                                | 2929 |
| F.29.2. EXPLAIN (RANGE_TABLE) .....                                                          | 2930 |
| F.29.3. Author .....                                                                         | 2930 |
| F.30. <code>pg_prewarm</code> — preload relation data into buffer caches .....               | 2931 |
| F.30.1. Functions .....                                                                      | 2931 |
| F.30.2. Configuration Parameters .....                                                       | 2931 |
| F.30.3. Author .....                                                                         | 2932 |
| F.31. <code>pgrowlocks</code> — show a table's row locking information .....                 | 2933 |
| F.31.1. Overview .....                                                                       | 2933 |
| F.31.2. Sample Output .....                                                                  | 2934 |
| F.31.3. Author .....                                                                         | 2934 |
| F.32. <code>pg_stat_statements</code> — track statistics of SQL planning and execution ..... | 2935 |
| F.32.1. The <code>pg_stat_statements</code> View .....                                       | 2935 |
| F.32.2. The <code>pg_stat_statements_info</code> View .....                                  | 2939 |
| F.32.3. Functions .....                                                                      | 2940 |
| F.32.4. Configuration Parameters .....                                                       | 2940 |
| F.32.5. Sample Output .....                                                                  | 2941 |
| F.32.6. Authors .....                                                                        | 2943 |
| F.33. <code>pgstattuple</code> — obtain tuple-level statistics .....                         | 2944 |
| F.33.1. Functions .....                                                                      | 2944 |
| F.33.2. Authors .....                                                                        | 2948 |
| F.34. <code>pg_surgery</code> — perform low-level surgery on relation data .....             | 2949 |
| F.34.1. Functions .....                                                                      | 2949 |
| F.34.2. Authors .....                                                                        | 2950 |
| F.35. <code>pg_trgm</code> — support for similarity of text using trigram matching .....     | 2951 |
| F.35.1. Trigram (or Trigraph) Concepts .....                                                 | 2951 |
| F.35.2. Functions and Operators .....                                                        | 2951 |
| F.35.3. GUC Parameters .....                                                                 | 2953 |
| F.35.4. Index Support .....                                                                  | 2953 |
| F.35.5. Text Search Integration .....                                                        | 2955 |
| F.35.6. References .....                                                                     | 2956 |
| F.35.7. Authors .....                                                                        | 2956 |
| F.36. <code>pg_visibility</code> — visibility map information and utilities .....            | 2957 |
| F.36.1. Functions .....                                                                      | 2957 |
| F.36.2. Author .....                                                                         | 2958 |
| F.37. <code>pg_walinspect</code> — low-level WAL inspection .....                            | 2959 |
| F.37.1. General Functions .....                                                              | 2959 |
| F.37.2. Author .....                                                                         | 2962 |
| F.38. <code>postgres_fdw</code> — access data stored in external PostgreSQL servers .....    | 2963 |
| F.38.1. FDW Options of <code>postgres_fdw</code> .....                                       | 2963 |
| F.38.2. Functions .....                                                                      | 2969 |
| F.38.3. Connection Management .....                                                          | 2971 |
| F.38.4. Transaction Management .....                                                         | 2971 |
| F.38.5. Remote Query Optimization .....                                                      | 2972 |
| F.38.6. Remote Query Execution Environment .....                                             | 2972 |
| F.38.7. Cross-Version Compatibility .....                                                    | 2972 |
| F.38.8. Wait Events .....                                                                    | 2973 |
| F.38.9. Configuration Parameters .....                                                       | 2973 |
| F.38.10. Examples .....                                                                      | 2974 |
| F.38.11. Author .....                                                                        | 2974 |
| F.39. <code>seg</code> — a datatype for line segments or floating point intervals .....      | 2975 |
| F.39.1. Rationale .....                                                                      | 2975 |
| F.39.2. Syntax .....                                                                         | 2975 |
| F.39.3. Precision .....                                                                      | 2976 |
| F.39.4. Usage .....                                                                          | 2976 |
| F.39.5. Notes .....                                                                          | 2977 |

|                                                                                                       |      |
|-------------------------------------------------------------------------------------------------------|------|
| F.39.6. Credits .....                                                                                 | 2977 |
| F.40. sepgsql — SELinux-, label-based mandatory access control (MAC) security module .....            | 2978 |
| F.40.1. Overview .....                                                                                | 2978 |
| F.40.2. Installation .....                                                                            | 2978 |
| F.40.3. Regression Tests .....                                                                        | 2979 |
| F.40.4. GUC Parameters .....                                                                          | 2980 |
| F.40.5. Features .....                                                                                | 2981 |
| F.40.6. Sepsqql Functions .....                                                                       | 2984 |
| F.40.7. Limitations .....                                                                             | 2985 |
| F.40.8. External Resources .....                                                                      | 2985 |
| F.40.9. Author .....                                                                                  | 2985 |
| F.41. spi — Server Programming Interface features/examples .....                                      | 2987 |
| F.41.1. refint — Functions for Implementing Referential Integrity .....                               | 2987 |
| F.41.2. autoinc — Functions for Autoincrementing Fields .....                                         | 2987 |
| F.41.3. insert_username — Functions for Tracking Who Changed a Table .....                            | 2988 |
| F.41.4. moddatetime — Functions for Tracking Last Modification Time .....                             | 2988 |
| F.42. sslinfo — obtain client SSL information .....                                                   | 2989 |
| F.42.1. Functions Provided .....                                                                      | 2989 |
| F.42.2. Author .....                                                                                  | 2990 |
| F.43. tablefunc — functions that return tables ( <code>crosstab</code> and others) .....              | 2991 |
| F.43.1. Functions Provided .....                                                                      | 2991 |
| F.43.2. Author .....                                                                                  | 3000 |
| F.44. tcn — a trigger function to notify listeners of changes to table content .....                  | 3001 |
| F.45. test_decoding — SQL-based test/example module for WAL logical decoding .....                    | 3003 |
| F.46. tsm_system_rows — the <code>SYSTEM_ROWS</code> sampling method for <code>TABLESAMPLE</code> ..  | 3004 |
| F.46.1. Examples .....                                                                                | 3004 |
| F.47. tsm_system_time — the <code>SYSTEM_TIME</code> sampling method for <code>TABLESAMPLE</code> ... | 3005 |
| F.47.1. Examples .....                                                                                | 3005 |
| F.48. unaccent — a text search dictionary which removes diacritics .....                              | 3006 |
| F.48.1. Configuration .....                                                                           | 3006 |
| F.48.2. Usage .....                                                                                   | 3007 |
| F.48.3. Functions .....                                                                               | 3008 |
| F.49. uuid-ossdp — a UUID generator .....                                                             | 3009 |
| F.49.1. uuid-ossdp Functions .....                                                                    | 3009 |
| F.49.2. Building uuid-ossdp .....                                                                     | 3010 |
| F.49.3. Author .....                                                                                  | 3010 |
| F.50. xml2 — XPath querying and XSLT functionality .....                                              | 3011 |
| F.50.1. Deprecation Notice .....                                                                      | 3011 |

# Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard's conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A.1 lists all the error codes defined in PostgreSQL 18.4. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

**Table A.1. PostgreSQL Error Codes**

| Error Code                                                                    | Condition Name                             |
|-------------------------------------------------------------------------------|--------------------------------------------|
| <b>Class 00 — Successful Completion</b>                                       |                                            |
| 00000                                                                         | successful_completion                      |
| <b>Class 01 — Warning</b>                                                     |                                            |
| 01000                                                                         | warning                                    |
| 0100C                                                                         | dynamic_result_sets_returned               |
| 01008                                                                         | implicit_zero_bit_padding                  |

# Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

## B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
  - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
  - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., `America/New_York`).
  - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., `19990113` for January 13, 1999) or time (e.g., `141516` for 14:15:16).
  - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
  - a. See if the token matches any known time zone abbreviation. These abbreviations are determined by the configuration settings described in Section B.4.
  - b. If not found, search an internal table to match the token as either a special string (e.g., `today`), day (e.g., `Thursday`), month (e.g., `January`), or noise word (e.g., `at`, `on`).
  - c. If still not found, throw an error.
3. When the token is a number or number field:
  - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., `19990118` or `990118`). The interpretation is `YYYYMM-MDD` or `YYMMDD`.
  - b. If the token is three digits and a year has already been read, then interpret as day of year.
  - c. If four or six digits and a year has already been read, then interpret as a time (`HHMM` or `HHMMSS`).
  - d. If three or more digits and no date fields have yet been found, interpret as a year (this forces `yy-mm-dd` ordering of the remaining date fields).
  - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: `mm-dd-yy`, `dd-mm-yy`, or `yy-mm-dd`. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

**Tip**

Gregorian years AD 1–99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

## B.2. Handling of Invalid or Ambiguous Time-stamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the `TimeZone` parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestampz;
      timestampz
-----
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. PostgreSQL interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 01:30'::timestampz;
      timestampz
-----
2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, PostgreSQL interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```
=> SELECT '2018-11-04 01:30 EDT'::timestampz;
      timestampz
-----
2018-11-04 01:30:00-04
(1 row)
```

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

## B.3. Date/Time Key Words

Table B.1 shows the tokens that are recognized as names of months.

**Table B.1. Month Names**

| Month     | Abbreviations |
|-----------|---------------|
| January   | Jan           |
| February  | Feb           |
| March     | Mar           |
| April     | Apr           |
| May       |               |
| June      | Jun           |
| July      | Jul           |
| August    | Aug           |
| September | Sep, Sept     |
| October   | Oct           |
| November  | Nov           |
| December  | Dec           |

Table B.2 shows the tokens that are recognized as names of days of the week.

**Table B.2. Day of the Week Names**

| Day       | Abbreviations    |
|-----------|------------------|
| Sunday    | Sun              |
| Monday    | Mon              |
| Tuesday   | Tue, Tues        |
| Wednesday | Wed, Weds        |
| Thursday  | Thu, Thur, Thurs |
| Friday    | Fri              |
| Saturday  | Sat              |

Table B.3 shows the tokens that serve various modifier purposes.

**Table B.3. Date/Time Field Modifiers**

| Identifier    | Description               |
|---------------|---------------------------|
| AM            | Time is before 12:00      |
| AT            | Ignored                   |
| JULIAN, JD, J | Next field is Julian Date |
| ON            | Ignored                   |
| PM            | Time is on or after 12:00 |
| T             | Next field is time        |

## B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted in datetime input. There are two sources for these abbreviations:

1. The `TimeZone` run-time parameter is usually set to the name of an entry in the IANA time zone database. If that zone has widely-used zone abbreviations, they will appear in the IANA data, and PostgreSQL will preferentially recognize those abbreviations with the meanings given in the IANA data. For example, if `timezone` is set to `America/New_York` then `EST` will be understood as UTC-5 and `EDT` will be understood as UTC-4. (These IANA abbreviations will also be used in datetime output, if `DateStyle` is set to a style that prefers non-numeric zone abbreviations.)
2. If an abbreviation is not found in the current IANA time zone, it is sought in the list specified by the `timezone_abbreviations` run-time parameter. The `timezone_abbreviations` list is primarily useful for allowing datetime input to recognize abbreviations for time zones other than the current zone. (These abbreviations will not be used in datetime output.)

While the `timezone_abbreviations` parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezone-sets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A *zone\_abbreviation* is just the abbreviation being defined. An *offset* is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a *time\_zone\_name* can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

### Tip

Using a simple integer *offset* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same time-zone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc., containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `time-zone_abbreviations` settings, because of the dot embedded in their names.

### Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

### Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

### Caution

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

## B.5. POSIX Time Zone Specifications

PostgreSQL can accept time zone specifications that are written according to the POSIX standard's rules for the `TZ` environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

*STD offset [ DST [ dstoffset ] [ , rule ] ]*

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- *STD* is the zone abbreviation to be used for standard time.
- *offset* is the zone's standard-time offset from UTC.
- *DST* is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.

- *dstoffset* is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time *offset*, which is usually the right thing.
- *rule* defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as `EST`, or an arbitrary string surrounded by angle brackets, such as `<UTC-05>`. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in Section B.4.

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format *hh[:mm[:ss]]* optionally with a leading sign (+ or -). The positive sign is used for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in PostgreSQL.) *hh* can have one or two digits; *mm* and *ss* (if used) must have two.

The daylight-savings transition *rule* has the format

*dstdate* [ / *dsttime* ] , *stddate* [ / *stdtime* ]

(As before, spaces should not be included in practice.) The *dstdate* and *dsttime* fields define when daylight-savings time starts, while *stddate* and *stdtime* define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

*n*

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

*Jn*

In this form, *n* counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

*Mm.n.d*

This form specifies a transition that always happens during the same month and on the same day of the week. *m* identifies the month, from 1 to 12. *n* specifies the *n*'th occurrence of the weekday identified by *d*. *n* is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). *d* is a number between 0 and 6, with 0 indicating Sunday. For example, `M3.2.0` means "the second Sunday in March".

### Note

The `M` format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to `02:00:00`.

If a daylight-savings abbreviation is given but the transition *rule* field is omitted, the fallback behavior is to use the rule `M3.2.0,M11.1.0`, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both

transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, CET - 1CEST, M3.5.0, M10.5.0/3 describes the current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation CET and is one hour ahead (east) of UTC; daylight savings time has the abbreviation CEST and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names EST5EDT, CST6CDT, MST7MDT, and PST8PDT look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, SET TIMEZONE TO FOOBAR0 will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

## B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as  $365 \frac{1}{4}$  days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as  $365 + 97 / 400$  days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation  $365+97/400$  is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.

However, every year divisible by 100 is not a leap year.

However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the `cal` program produce the following:

```
$ cal 9 1752
      September 1752
S  M Tu  W Th  F  S
      1  2 14 15 16
```

17 18 19 20 21 22 23  
24 25 26 27 28 29 30

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

## B.7. Julian Dates

The *Julian Date* system is a method for numbering days. It is unrelated to the Julian calendar, though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540–1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484–1558).

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from local midnight to local midnight, the same as a normal date.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone UTC+12. For example,

```
=> SELECT extract(julian from '2021-06-23 7:00:00-04'::timestampz
    at time zone 'UTC+12');
    extract
-----
2459388.95833333333333333333333333
(1 row)
=> SELECT extract(julian from '2021-06-23 8:00:00-04'::timestampz
    at time zone 'UTC+12');
    extract
-----
2459389.00000000000000000000000000000000
(1 row)
=> SELECT extract(julian from date '2021-06-23');
    extract
-----
2459389
(1 row)
```

---

# Appendix C. SQL Key Words

Table C.1 lists all tokens that are key words in the SQL standard and in PostgreSQL 18.4. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In Table C.1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by PostgreSQL.

Furthermore, while most key words can be used as “bare” column labels without writing `AS` before them (as described in Section 7.3.2), there are a few that require a leading `AS` to avoid ambiguity. These are marked in the table as “requires AS”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying Table C.1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

**Table C.1. SQL Key Words**

| Key Word  | PostgreSQL   | SQL:2023     | SQL:2016     | SQL-92       |
|-----------|--------------|--------------|--------------|--------------|
| A         |              | non-reserved | non-reserved |              |
| ABORT     | non-reserved |              |              |              |
| ABS       |              | reserved     | reserved     |              |
| ABSENT    | non-reserved | reserved     | reserved     |              |
| ABSOLUTE  | non-reserved | non-reserved | non-reserved | reserved     |
| ACCESS    | non-reserved |              |              |              |
| ACCORDING |              | non-reserved | non-reserved |              |
| ACOS      |              | reserved     | reserved     |              |
| ACTION    | non-reserved | non-reserved | non-reserved | reserved     |
| ADA       |              | non-reserved | non-reserved | non-reserved |

| Key Word              | PostgreSQL                         | SQL:2023     | SQL:2016     | SQL-92   |
|-----------------------|------------------------------------|--------------|--------------|----------|
| ADD                   | non-reserved                       | non-reserved | non-reserved | reserved |
| ADMIN                 | non-reserved                       | non-reserved | non-reserved |          |
| AFTER                 | non-reserved                       | non-reserved | non-reserved |          |
| AGGREGATE             | non-reserved                       |              |              |          |
| ALL                   | reserved                           | reserved     | reserved     | reserved |
| ALLOCATE              |                                    | reserved     | reserved     | reserved |
| ALSO                  | non-reserved                       |              |              |          |
| ALTER                 | non-reserved                       | reserved     | reserved     | reserved |
| ALWAYS                | non-reserved                       | non-reserved | non-reserved |          |
| ANALYSE               | reserved                           |              |              |          |
| ANALYZE               | reserved                           |              |              |          |
| AND                   | reserved                           | reserved     | reserved     | reserved |
| ANY                   | reserved                           | reserved     | reserved     | reserved |
| ANY_VALUE             |                                    | reserved     |              |          |
| ARE                   |                                    | reserved     | reserved     | reserved |
| ARRAY                 | reserved, requires AS              | reserved     | reserved     |          |
| ARRAY_AGG             |                                    | reserved     | reserved     |          |
| ARRAY_MAX_CARDINALITY |                                    | reserved     | reserved     |          |
| AS                    | reserved, requires AS              | reserved     | reserved     | reserved |
| ASC                   | reserved                           | non-reserved | non-reserved | reserved |
| ASENSITIVE            | non-reserved                       | reserved     | reserved     |          |
| ASIN                  |                                    | reserved     | reserved     |          |
| ASSERTION             | non-reserved                       | non-reserved | non-reserved | reserved |
| ASSIGNMENT            | non-reserved                       | non-reserved | non-reserved |          |
| ASYMMETRIC            | reserved                           | reserved     | reserved     |          |
| AT                    | non-reserved                       | reserved     | reserved     | reserved |

# Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2023. The 2023 version is referred to as ISO/IEC 9075:2023, or simply as SQL:2023. The versions prior to that were SQL:2016, SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard is split into a number of parts, each also known by a shorthand name:

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
- ISO/IEC 9075-16 Property Graph Queries (SQL/PGQ)

Note that some part numbers are not (or no longer) used.

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, 15, and 16 for PostgreSQL.

PostgreSQL supports most of the major features of SQL:2023. Out of 177 mandatory features required for full Core conformance, PostgreSQL conforms to at least 170. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2023.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2023 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

### Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

## D.1. Supported Features

| Identifier | Core? | Description                                       | Comment                                                     |
|------------|-------|---------------------------------------------------|-------------------------------------------------------------|
| B012       |       | Embedded C                                        |                                                             |
| B021       |       | Direct SQL                                        |                                                             |

## D.2. Unsupported Features

The following features defined in SQL:2023 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.

## D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. PostgreSQL's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type XML ( SEQUENCE ) to hold arbitrary pieces of XML content, PostgreSQL provides the single xml type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- PostgreSQL provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

- PostgreSQL does not support the `RETURNING CONTENT` or `RETURNING SEQUENCE` clauses, functions which are defined to have these in the specification are implicitly returning content.

This section presents some of the resulting differences you may encounter.

## D.3.1. Queries Are Restricted to XPath 1.0

The PostgreSQL-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. PostgreSQL also provides XPath-only variants of the standard functions `XML-EXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, PostgreSQL relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the PostgreSQL-specific functions.

### D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

### D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the **sequence**, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

#### Note

The libxml2 library does seem to always return node-sets to PostgreSQL with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat/@size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any PostgreSQL XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of function library changes<sup>1</sup> and language changes<sup>2</sup> applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

### D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When PostgreSQL maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, PostgreSQL simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in Section 9.8) explicitly to produce the standard mappings.

## D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in PostgreSQL.

### D.3.2.1. Only BY VALUE Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

---

<sup>1</sup> <https://www.w3.org/TR/2010/REC-xpath-functions-20101214/#xpath1-compatibility>

<sup>2</sup> <https://www.w3.org/TR/xpath20/#id-backwards-compatibility>

To illustrate the difference, if *x* is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON  
EMPTY);  
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON  
EMPTY);
```

PostgreSQL will accept `BY VALUE` or `BY REF` in an `XMLEXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

### **D.3.2.2. Cannot Pass Named Parameters to Queries**

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

### **D.3.2.3. No XML (SEQUENCE) Type**

The PostgreSQL `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that PostgreSQL can supply as an XPath context item.

---

# Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list<sup>1</sup> records all source code changes as well. There is also a web interface<sup>2</sup> that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

## E.1. Release 18.4

**Release date:** 2026-05-14

This release contains a variety of fixes from 18.3. For information about new features in major release 18, see Section E.5.

### E.1.1. Migration to Version 18.4

A dump/restore is not required for those running 18.X.

However, if you are upgrading from a version earlier than 18.2, see Section E.3.

### E.1.2. Changes

- Prevent unbounded recursion while processing startup packets (Michael Paquier)

A malicious client could crash the connected backend by alternating rejected SSL and GSS encryption requests indefinitely.

The PostgreSQL Project thanks Calif.io (in collaboration with Claude and Anthropic Research) for reporting this problem. (CVE-2026-6479)

- Fix assorted integer overflows in memory-allocation calculations (Tom Lane, Nathan Bossart, Heikki Linnakangas)

Various places were incautious about the possibility of integer overflow in calculations of how much memory to allocate. Overflow would lead to allocating a too-small buffer which the caller would then write past the end of. This would at least trigger server crashes, and probably could be exploited for arbitrary code execution. In many but by no means all cases, the hazard exists only in 32-bit builds.

The PostgreSQL Project thanks Xint Code, Bruce Dang, Sven Klemm, and Pavel Kohout for reporting these problems. (CVE-2026-6473)

- Properly quote subscription names in `pg_createsubscriber` (Nathan Bossart)

The given subscription name was inserted into SQL commands without quoting, so that SQL injection could be achieved in the (perhaps unlikely) case that the subscription name comes from an untrusted source.

The PostgreSQL Project thanks Yu Kunpeng for reporting this problem. (CVE-2026-6476)

---

<sup>1</sup> <https://www.postgresql.org/list/pgsql-committers/>

<sup>2</sup> <https://git.postgresql.org/gitweb/?p=postgresql.git;a=summary>

- Properly quote object names in logical replication origin checks (Pavel Kohout)

`ALTER SUBSCRIPTION ... REFRESH PUBLICATION` interpolated schema and relation names into SQL commands without quoting them, allowing execution of arbitrary SQL on the publisher.

The PostgreSQL Project thanks Pavel Kohout for reporting this problem. (CVE-2026-6638)

- Reject over-length options in `ts_headline()` (Michael Paquier)

The `StartSel`, `StopSel` and `FragmentDelimiter` strings must not exceed 32Kb in length, but this was not checked for. An over-length value would typically crash the server.

The PostgreSQL Project thanks Xint Code for reporting this problem. (CVE-2026-6473)

- Detect faulty input when restoring attribute MCV statistics (Michael Paquier)

The statistics restore functions were insufficiently careful about validating most-common-value statistics, and would accept values that could crash the planner later on.

The PostgreSQL Project thanks Jeroen Gui for reporting this problem. (CVE-2026-6575)

- Guard against malicious time zone names in `timeofday()` and `pg_strftime()` (Tom Lane)

A crafted time zone setting could pass % sequences to `snprintf()`, potentially causing crashes or disclosure of server memory. Another path to similar results was to overflow the limited-size output buffer used by `pg_strftime()`.

The PostgreSQL Project thanks Xint Code for reporting this problem. (CVE-2026-6474)

- When creating a multirange type, ensure the user has `CREATE` privilege on the schema specified for the multirange type (Jelte Fennema-Nio)

The multirange type can be put into a different schema than its parent range type, but we neglected to apply the required privilege check when doing so.

The PostgreSQL Project thanks Jelte Fennema-Nio for reporting this problem. (CVE-2026-6472)

- Use timing-safe string comparisons in authentication code (Michael Paquier)

Use `timingsafe_bcmp()` instead of `memcpy()` or `strcmp()` when checking passwords, hashes, etc. It is not known whether the data dependency of those functions is usefully exploitable in any of these places, but in the interests of safety, replace them.

The PostgreSQL Project thanks Joe Conway for reporting this problem. (CVE-2026-6478)

- Mark `PQfn()` as unsafe, and avoid using it within libpq (Nathan Bossart)

For a non-integral result type, `PQfn()` is not passed the size of the output buffer, so it cannot check that the data returned by the server will fit. A malicious server could therefore overwrite client memory. This is unfixable without an API change, so mark the function as deprecated. Internally to libpq, use a variant version that can apply the missing check.

The PostgreSQL Project thanks Yu Kunpeng and Martin Heistermann for reporting this problem. (CVE-2026-6477)

- Prevent path traversal in `pg_basebackup` and `pg_rewind` (Michael Paquier)

These applications failed to validate output file paths read from their input, so that a malicious source could overwrite any file writable by these applications. Constrain where data can be written by rejecting paths that are absolute or contain parent-directory references.

The PostgreSQL Project thanks XlabAI Team of Tencent Xuanwu Lab and Valery Gubanov for reporting this problem. (CVE-2026-6475)

- Guard against field overflow within `contrib/intarray`'s `query_int` type and `contrib/ltree`'s `ltxquery` type (Tom Lane)

Parsing of these query structures did not check for overflow of 16-bit fields, so that construction of an invalid query tree was possible. This can crash the server when executing the query.

The PostgreSQL Project thanks Xint Code for reporting this problem. (CVE-2026-6473)

- Guard against overly long values of `contrib/ltree`'s `lquery` type (Michael Paquier)

Values with more than 64K items caused internal overflows, potentially resulting in stack smashes or wrong answers.

The PostgreSQL Project thanks Vergissmeinnicht, Alex, and Jihe Wang for reporting this problem. (CVE-2026-6473)

- Prevent SQL injection and buffer overruns in `contrib/spi` (Nathan Bossart)

`check_foreign_key()` was insufficiently careful about quoting key values, and also used fixed-length buffers for constructing queries. While this module is only meant as example code, it still shouldn't contain such dangerous errors.

The PostgreSQL Project thanks Nikolay Samokhvalov for reporting this problem. (CVE-2026-6637)

- Check for nondeterministic collations before assuming that an equality condition on a collatable type implies uniqueness (Richard Guo)

Numerous planner optimizations assume that, for example, at most one table row can satisfy `WHERE x = 'abc'` if there is a unique index on `x`. However this conclusion is unsafe in general if the index and the `WHERE` clause have different collations attached. It is safe when both collations are deterministic, because that property essentially requires that equality of two strings means bitwise equality. But nondeterministic collations don't act that way, so that optimizing on the assumption of unique matches can give wrong query answers if either the `WHERE` clause or the index has a nondeterministic collation.

- Fix incomplete removal of relation references in `RestrictInfo` structs during join removal (Tom Lane)

This oversight has been shown to result in planner failures such as unexpected “FULL JOIN is only supported with merge-joinable or hash-joinable join conditions” errors. It may also have caused failure to consider valid plans in other cases.

- Improve planner's matching of partition key columns to sub-query outputs (Richard Guo)

Strip no-op `PlaceholderVars` from operands before comparing them to partition keys. This change enables partition pruning to succeed in some cases where it previously failed to recognize that a partition need not be scanned.

- Fix self-join removal to handle join clauses that are bare boolean columns, e.g. `ON t1.boolcol` (Andrei Lepikhov, Tender Wang, Alexander Korotkov)

Previously such a case led to a “no relation entry for relid *N*” error.

- Fix `UPDATE/DELETE ... WHERE CURRENT OF` to work on tables with virtual generated columns (Satyanarayana Narlapuram, Dean Rasheed)

- Fix expansion of virtual generated columns in `EXCLUDED` column references in `INSERT ... ON CONFLICT` (Satyanarayana Narlapuram, Dean Rasheed)
- Fix incorrect handling of `NEW` generated columns in rule actions and rule qualifications (Richard Guo, Dean Rasheed)

Previously, such column references would produce `NULL` in `INSERT` cases, or be equivalent to the `OLD` value in `UPDATE` cases.

- Fix spurious “indexes on virtual generated columns are not supported” errors (Robert Haas)
- Fix spurious “generated columns are not supported in `COPY FROM WHERE` conditions” errors (Tom Lane)

Creation of an expression index could sometimes incorrectly report this error.

Use of a system column in a `COPY FROM WHERE` condition could sometimes incorrectly report this error.

- Correctly report a serialization failure when `MERGE` encounters a concurrently-updated tuple in repeatable-read or serializable mode (Tender Wang)

Previously, such cases behaved the same as in lower isolation levels.

- Fix `CREATE TABLE ... LIKE ... INCLUDING STATISTICS` for cases where the source table has dropped column(s) (Julien Tachaires)

In such cases, extended statistics objects could be copied incorrectly, or the command could give an incorrect error.

- Allow `ALTER INDEX ... ATTACH PARTITION` to mark the parent index valid if appropriate (Sami Imseih)

There are edge cases in which a partitioned index might remain marked as invalid even when all its leaf indexes are valid. This change provides a mechanism whereby a user can correct such a situation without resorting to manual catalog updates.

- Fix `ALTER TABLE ... SET NOT NULL` to invoke object-access hook functions only after completing the catalog change (Artur Zakirov)
- Fix `ALTER FOREIGN DATA WRAPPER` to not drop the wrapper object's dependency on its handler function (Jeff Davis)
- Fix loss of deferrability of foreign-key triggers (Yasuo Honda)

Previously, a foreign key defined as `DEFERRABLE INITIALLY DEFERRED` would behave as `NOT DEFERRABLE` after being set to `NOT ENFORCED` status and then back to `ENFORCED`.

If you have a foreign key with this problem, it can be repaired (after installing this update) by again setting it to `NOT ENFORCED` and then back to `ENFORCED`.

- Fix `WITHOUT OVERLAPS` to allow domains (Jian He)

`UNIQUE/PRIMARY KEY ... WITHOUT OVERLAPS` requires the no-overlap column to be a range or multirange, but it should allow a domain over such a type too.

- Disallow making a composite type be a member of itself via a multirange (Heikki Linnakangas)

We already forbade such cases when the intermediate type is a domain, array, composite type, or range; but multiranges were overlooked.

- Fix datum-image comparisons to be insensitive to sign-extension variations (David Rowley)

This fixes some situations that previously led to “could not find memoization table entry” errors or wrong query results.

- Fix incorrect logic for hashed `IN/NOT IN` with non-strict equality operator (Chengpeng Yan)

The previous coding could crash or give wrong answers. All built-in data types have strict equality operators, so that this issue could only arise with an extension data type.

- Truncate overly-long locale-specific numeric symbols in `to_char()` (Tom Lane)

If a locale specified a currency symbol, thousands separator, or decimal or sign symbol more than 8 bytes long, a buffer overrun was possible. No such locales exist in the real world, and it's impractical for an unprivileged attacker to install a malicious locale definition underneath a Postgres server; but for safety's sake check for overlength symbols and truncate if needed.

- Prevent buffer overruns when parsing an affix file for an `IsPELL` dictionary (Tom Lane)

A corrupt or malicious affix file could crash the server. This is not considered a security issue because text search configuration files are presumed trustworthy, but it still seems worth fixing.

- Guard against integer overflow in calculations of frame start and end positions for window aggregates (Richard Guo)

Very large user-specified offsets (close to `INT64_MAX`) could result in errors or incorrect query results.

- Fix `array_agg_array_combine()` to combine the arrays' null bitmaps correctly (Dmytro Astapov)

This mistake resulted in sometimes-incorrect output from parallelized `array_agg(anyarray)` calculations.

- Retry `sync_file_range()` if it returns error code `EINTR` (DaeMyung Kang)

- Fix incorrect behavior of `pg_stat_reset_single_table_counters()` on a shared catalog (Chao Li)

Such cases had a side-effect of resetting the current database's `stat_reset_timestamp`, which was unintended.

- Update activity statistics when a parallel apply worker is idle (Zhijie Hou)

Previously, statistics from a recently-completed transaction might go unreported for long intervals, particularly if the workload is light.

- Fix “no relation entry for relid 0” failure while estimating array lengths in set operations (Tender Wang)

- Fix buffer overread when `pg_lz_decompress()` receives corrupt input (Andrew Dunstan)

It was possible to read a few bytes past the end of the input, which in very unlucky cases might cause a crash.

- Fix incremental JSON parser's handling of numeric tokens that cross input buffer boundaries (Andrew Dunstan)

It was possible to accept an incorrectly-formatted number, leading to failures later.

- Prevent bloating relation visibility maps during restore of an incremental backup (Robert Haas)

Restore could append many blocks of zeroes to a visibility map, due to incorrect computation of the expected file length. This does not result in data corruption, but it could waste a substantial amount of disk space.

- Use C collation, not the database's default collation, in catalog cache lookups on text columns (Jeff Davis)

This avoids failures in edge cases such as physical replication startup, where there is no identified database so that a default collation cannot be determined.

- Prevent stuck slotsync worker processes from blocking promotion of a standby server (Nisha Moond, Ajin Cherian)

A worker process that was vainly waiting for a response from the primary would delay promotion for an unreasonable amount of time.

- Fix excessive log output from idle slotsync worker processes (Zhijie Hou)
- Ensure that tuplestore data structures are internally consistent even after an error (Tom Lane)

The code was previously careless about this, which is fine most of the time but is problematic for the tuplestore backing a `WITH HOLD` cursor. In v15 and before this leads to easily-reproducible crashes; later branches are not known to be vulnerable, but it seems best to preserve consistency in all.

- Make the `pg_aio` system view's `pid` column show NULL not 0 when an entry has no owning process (ChangAo Chen)
- Fix premature NULL lag reporting in `pg_stat_replication` (Shinya Kato)

The lag columns frequently read as NULL even while replication activity was happening.

- Fix under-allocation of shared memory used for parallel btree index scans (Siddharth Kothari)

In edge cases this could result in a server crash.

- Avoid rare flush failure when working with non-WAL-logged GiST indexes (Tomas Vondra)

A non-logged GiST index could nonetheless sometimes produce “xlog flush request *n/nnnn* is not satisfied” errors, due to incorrect selection of a “fake LSN” to represent an insertion point.

- Fix underestimate of required size of DSA page maps for odd-size segments (Paul Bunn)

This miscalculation led to out-of-bounds accesses and hence server crashes.

- Fix indexing of oldest-multixact arrays in shared memory (Yura Sokolov)

This mistake could cause a prepared-but-not-yet-committed transaction's row locks to appear invisible to other sessions, or other visibility issues for the results of such a transaction. With a very small `max_connections` setting, memory stomps were also possible.

- Fix array overrun when too many `EXPLAIN` extension options are installed (Joel Jacobson)
- Fix possible server crash when processing extended statistics on expressions of extension data types (Michael Paquier)

NULL pointer dereferences were possible if the data type's `tyanalyze` function does not compute any useful statistics. No in-core `tyanalyze` function behaves that way, but extensions could.

- Correctly display join alias Vars that are used in `GROUP BY` (Tom Lane)

In views containing queries like `SELECT ... t1 LEFT JOIN t2 USING (x) GROUP BY x`, the `GROUP BY` clause could be displayed incorrectly by deparsing, leading to dump/restore

failures. Failures occurred only if `t1.x` and `t2.x` were not of identical data types and `t1.x` was the side that required an implicit coercion.

- Fix minor memory leaks in ICU-based string processing (Jeff Davis)
- If the startup process fails, properly shut down other child processes before exiting the postmaster (Ayush Tiwari)

The handling of this situation relied on a long-obsolete assumption that no other postmaster children exist while the startup process is running, so that immediate postmaster exit is acceptable. Orphaned children would eventually notice the postmaster's death and exit on their own, but a cleaner shut-down procedure is desirable.

- Fix race condition between WAL replay of checkpoints and multixact ID creations (Heikki Lin-nakangas)

A standby server following WAL from a primary of an older minor version could get into a crash-and-restart loop complaining about “could not access status of transaction”.

- Prevent indefinite wait in shutdown of a walsender process (Anthonin Bonnefoy)

At shutdown of a cluster that is publishing logical replication data, the walsender waits for all pending WAL to be written out. But it did not correctly request that to happen, so that in some cases this could become an indefinite wait.

- Ensure that changes to tables' free space maps are persisted during recovery (Alexey Makhmutov)

Previously, while WAL replay did update the free space map while replaying operations that should change it, the map page buffer did not get marked dirty if checksums are enabled, so that the changes might never get written out. On a standby server, over time this would result in a map wildly at variance with the table's actual contents. While the map is only used as a hint, this condition could cause significant performance degradation for some period of time after the standby server is promoted to be active, until most of the map has been repaired by updates.

- Fix crashes in some `ecpg` functions when called without any established connection (Shruthi Gowda)
- Harden tar-file parsing logic against archives it can't handle (Tom Lane)

The tar-file reading code used in `pg_basebackup` and `pg_verifybackup` failed to verify that the input is a tar file at all, let alone that it fits into the subset of valid tar files that we can handle. This isn't a problem for the normal scenario where the input file was generated by PostgreSQL code, but it can be an issue if the input has been generated by some other tar program.

- Fix assorted bugs in backup decompression and tar-parsing code (Andrew Dunstan, Tom Lane, Chao Li)

The decompression and tar-file reading code used in `pg_basebackup` and `pg_verifybackup` mishandled tar-file padding data, could corrupt LZ4-compressed data in edge cases, failed to check for some unusual error conditions, failed to exit after compression/decompression errors (leading to cascading error reports), and leaked memory.

- In `pg_dump`, preserve `NO INHERIT` property of `NOT NULL` constraints (Jian He)

Some cases missed printing the `NO INHERIT` clause.

- In `pg_dumpall`, don't skip role `GRANT`s with dangling grantor OIDs (Tom Lane)

Instead, handle such cases by emitting `GRANT` without any `GRANTED BY` clause, as we did before v16. This avoids losing the grant in foreseeable cases, since pre-v16 servers didn't prevent dropping the grantor role. Continue to emit a warning about the missing grantor, but only if the source server is v16 or later.

- In `pg_upgrade`, take care to use the correct protocol version when connecting to older source servers (Jacob Champion)

This could be problematic when attempting to upgrade from a pre-2018 server.

- In `contrib/basic_archive`, allow the archive directory to be missing at startup (Nathan Bossart)

Previously, the setting of `basic_archive.archive_directory` was rejected if it didn't point to an existing directory. This is undesirable because archiving will be stuck indefinitely, even if the directory appears later.

- Fix `contrib/ltree` to cope when case-folding changes a string's byte length (Jeff Davis)

Previously, `lquery` patterns specifying case-insensitive matching might fail to match labels they should match.

- Fix mis-structured output from `contrib/pg_overexplain`'s `RANGE_TABLE` option (Satya-narayana Narlapuram)

Some fields were misplaced in JSON, YAML, and XML formats, resulting in structurally invalid output.

- In `contrib/pg_stat_statements`, don't leak memory if an error occurs while parsing the `pgss_query_texts.stat` file (Heikki Linnakangas)

- In `contrib/postgres_fdw`, avoid crash due to premature cleanup of a failed connection (Etsuro Fujita)

If a remote connection fails abort cleanup, we can't use it any longer. But delay closing the connection object until end of transaction, because there might still be references to it within data structures such as open cursors.

- Update time zone data files to tzdata release 2026b (Tom Lane)

British Columbia (America/Vancouver) will be on year-round UTC-07 (effectively, permanent DST) beginning in November 2026. This release assumes that their TZ abbreviation will be MST from that time forward. That seems likely to change, but it's unclear what new abbreviation will be used. Also a historical correction for Moldova: they have followed EU DST transition times since 2022.

## E.2. Release 18.3

**Release date:** 2026-02-26

This release contains a small number of fixes from 18.2. For information about new features in major release 18, see Section E.5.

### E.2.1. Migration to Version 18.3

A dump/restore is not required for those running 18.X.

However, if you are upgrading from a version earlier than 18.2, see Section E.3.

### E.2.2. Changes

- Fix failure after replaying a multixid truncation record from WAL that was generated by an older minor version (Heikki Linnakangas)

Erroneous logic for coping with the way that previous versions handled multixid wraparound led to replay failure, with messages like “could not access status of transaction”. A typical scenario in which this could occur is a standby server of the latest minor version consuming WAL from a primary server of an older version.

- Avoid incorrect complaint of invalid encoding when `substring()` is applied to “toasted” data (Noah Misch)

The fix for CVE-2026-2006 was too aggressive and could raise an error about an incomplete character in cases that are actually valid.

- Fix oversight in the fix for CVE-2026-2007 (Zsolt Parragi)

If the “bounds” array needed to be expanded, because the input contained more trigrams than the initial guess, `generate_trgm_only` didn't return the modified array pointer to its caller. That would lead to incorrect output from `strict_word_similarity()` and related functions, or in rare cases a crash. The faulty code is reached if the input string becomes longer when it's converted to lower case. The only known instances of that occur when an ICU locale is used with certain single-byte encodings.

- Fix the volatility marking of `json_strip_nulls()` and `jsonb_strip_nulls()` (Andrew Dunstan)

These functions have always been considered immutable, but refactoring in version 18 accidentally marked them stable instead. That prevents their use in index expressions and could cause unnecessary repeat evaluations in queries. This fix corrects the marking in newly-initialized database clusters (including clusters that are `pg_upgrade`'d to 18.3 or later). However it will not help existing clusters made using 18.0 through 18.2.

If this mistake affects your usage of these functions, the recommended fix for an existing cluster is a manual catalog update. As superuser, perform

```
UPDATE pg_catalog.pg_proc SET provolatile = 'i' WHERE oid IN
('3261', '3262');
```

in each affected database. Update `template0` and `template1` as well, so that databases made in future will have the fix.

- Fix computation of the set of potentially-nulling outer joins for the output of a `LATERAL UNION ALL` subquery (Richard Guo)

This error could lead to skipping `NOT NULL` tests in the mistaken belief that they were unnecessary, resulting in wrong query output.

- Avoid name collisions between user-written constraints and automatically-named `NOT NULL` constraints (Laurenz Albe)

As of version 18, `NOT NULL` constraints have full-fledged `pg_constraint` entries, and therefore require names. The logic for choosing a name for an unnamed `NOT NULL` constraint failed to avoid conflicts with user-written constraints elsewhere in the same `CREATE TABLE` statement.

- Fix `pg_stat_get_backend_wait_event()` and `pg_stat_get_backend_wait_event_type()` to report values for auxiliary processes (Heikki Linnakangas)

Previously these functions returned `NULL` for auxiliary processes, but that's inconsistent with the `pg_stat_activity` view.

- Fix casting a composite-type variable to a domain type when returning its value from a PL/pgSQL function (Tom Lane)

If the variable's value is NULL, a “cache lookup failed for type 0” error resulted.

- Fix potential null pointer dereference in `contrib/hstore`'s binary input function (Michael Paquier)

`hstore`'s receive function crashed on input containing duplicate keys. `hstore` values generated by Postgres would never contain duplicate keys, so this mistake has gone unnoticed. The crash could be provoked by malicious or corrupted data.

## E.3. Release 18.2

**Release date:** 2026-02-12

This release contains a variety of fixes from 18.1. For information about new features in major release 18, see Section E.5.

### E.3.1. Migration to Version 18.2

A dump/restore is not required for those running 18.X.

However, if you have any indexes on `ltree` columns, it may be necessary to reindex them after updating. See the sixth changelog entry below.

### E.3.2. Changes

- Guard against unexpected dimensions of `oidvector/int2vector` (Tom Lane)

These data types are expected to be 1-dimensional arrays containing no nulls, but there are cast pathways that permit violating those expectations. Add checks to some functions that were depending on those expectations without verifying them, and could misbehave in consequence.

The PostgreSQL Project thanks Altan Birlir for reporting this problem. (CVE-2026-2003)

- Harden selectivity estimators against being attached to operators that accept unexpected data types (Tom Lane)

`contrib/intarray` contained a selectivity estimation function that could be abused for arbitrary code execution, because it did not check that its input was of the expected data type. Third-party extensions should check for similar hazards and add defenses using the technique `intarray` now uses. Since such extension fixes will take time, we now require superuser privilege to attach a non-built-in selectivity estimator to an operator.

The PostgreSQL Project thanks Daniel Firer, as part of zeroday.cloud, for reporting this problem. (CVE-2026-2004)

- Fix buffer overrun in `contrib/pgcrypto`'s PGP decryption functions (Michael Paquier)

Decrypting a crafted message with an overlength session key caused a buffer overrun, with consequences as bad as arbitrary code execution.

The PostgreSQL Project thanks Team Xint Code, as part of zeroday.cloud, for reporting this problem. (CVE-2026-2005)

- Fix inadequate validation of multibyte character lengths (Thomas Munro, Noah Misch)

Assorted bugs allowed an attacker able to issue crafted SQL to overrun string buffers, with consequences as bad as arbitrary code execution. After these fixes, applications may observe “invalid byte sequence for encoding” errors when string functions process invalid text that has been stored in the database.

The PostgreSQL Project thanks Paul Gerste and Moritz Sanft, as part of zeroday.cloud, for reporting this problem. (CVE-2026-2006)

- Harden `contrib/pg_trgm` against changes in string lowercasing behavior (Heikki Linnakangas)

Fix potential buffer overruns arising from the fact that in some locales lower-casing a string can produce more characters (not bytes) than were in the original. That behavior is new in version 18, and so is the bug.

The PostgreSQL Project thanks Heikki Linnakangas for reporting this problem. (CVE-2026-2007)

- Fix inconsistent case-insensitive matching in `contrib/ltree` (Jeff Davis)

Index-related routines in `ltree` used a different implementation of case-folding than the primary operators did. Their behavior was equivalent only if the default collation provider was `libc` and the encoding was single-byte.

To fix, change the code to use case-folding with the database's default collation. This change will require reindexing indexes on `ltree` columns (regardless of the index access method) unless the database uses `libc` as collation provider and its encoding is single-byte. Without that, searches of such indexes will fail to locate relevant entries.

- When using `ALTER TABLE ... ADD CONSTRAINT` to add a not-null constraint with an explicit name, if the column is already marked `NOT NULL`, require that the provided name match the existing constraint name (Álvaro Herrera, Srinath Reddy Sadipiralla)
- Don't allow CTE references in sub-selects to determine semantic levels of aggregate functions (Tom Lane)

This change undoes a change made two minor releases ago, instead throwing an error if a sub-select references a CTE that's below the semantic level that standard SQL rules would assign to the aggregate based on contained column references and aggregates. The attempted fix turned out to cause problems of its own, and it's unclear what to do instead. Since sub-selects within aggregates are disallowed altogether by the SQL standard, treating such cases as errors seems sufficient.

- Fix trigger transition table capture for `MERGE` in CTE queries (Dean Rasheed)

When executing a data-modifying CTE query containing both a `MERGE` and another DML operation on a table with statement-level `AFTER` triggers, the transition tables passed to the triggers would not include the rows affected by the `MERGE`, only those affected by the other operation(s).

- Fix incorrect pruning of rowmarks belonging to non-relation rangetable entries, such as subqueries (Dean Rasheed)

This led to incorrect results if a proposed row update needed to be modified by `EvalPlanQual` rechecking, as could happen if there was a concurrent update to that row.

- Fix failure when all children of a partitioned target table of an update or delete have been pruned (Amit Langote)

In such cases, the executor could report “could not find junk ctid column” errors, even though nothing needs to be done.

- Fix expression evaluation bug for a sub-select within an array subscript (Andres Freund)
- Fix text substring search for non-deterministic collations (Laurenz Albe)

When using a non-deterministic collation, we failed to detect a match occurring at the very end of the searched string.

- Avoid possible planner failure when a query contains duplicate window function calls (Meng Zhang, David Rowley)

Confusion over de-duplication of such calls could result in errors like “WindowFunc with winref 2 assigned to WindowAgg with winref 1”.

- Fix planner error with set-returning functions and grouping sets (Richard Guo)

When constructing a ProjectSet plan node, the planner failed to detect that subexpressions involving grouping expressions were already computed by the input plan. This led to inefficient plans or errors such as “variable not found in subplan target list”.

- Avoid incorrect optimization when a subquery's grouping clause contains a volatile or set-returning function (Richard Guo)

The planner was willing to push down outer-query restrictions referencing such a grouping column, leading to incorrect behavior due to multiple evaluation of a volatile function, or errors caused by introduction of a set-returning function into the subquery's WHERE/HAVING clauses.

- Look through PlaceholderVar nodes when searching for statistics about an expression (Richard Guo)

This change allows the planner to find relevant statistics about expressions pulled up from subqueries or used in GROUP BY, avoiding falling back to a default estimate. (Arguably we should adjust any found statistics to account for an increased probability of the value being NULL, but we've never done the equivalent thing for plain Vars either.) While this restriction is old, changes in PostgreSQL version 18 made PlaceholderVars more common than before, so make the change to avoid plan regressions in affected cases.

- Look through no-op PlaceholderVar nodes when matching expressions to indexes (Richard Guo)

Because PostgreSQL version 18 uses PlaceholderVars in more cases than before, some queries that formerly could use an index failed to do so. Add logic to prevent that regression.

- Fix planner's conversion of OR clauses to ScalarArrayOp index conditions (Tender Wang, Tom Lane)

The code did not handle RelabelType nodes correctly, and could generate invalid expressions or fail to perform a valid conversion.

- Allow indexscans on partial hash indexes even when the index's predicate implies the truth of the WHERE clause (Tom Lane)

Normally we drop a WHERE clause that is implied by the predicate, since it's pointless to test it; it must hold for every index entry. However that can prevent creation of an indexscan plan if the index is one that requires a WHERE clause on the leading index key, as hash indexes do. Don't drop implied clauses when considering such an index.

- Do not emit WAL for unlogged BRIN indexes (Kirill Reshke)

One seldom-taken code path incorrectly emitted a WAL record relating to a BRIN index even if the index was marked unlogged. Crash recovery would then fail to replay that record, complaining that the file already exists.

- Use the correct ordering function in parallel GIN index builds (Tomas Vondra)

The parallel code used the default ordering operator (which is determined by the column data type's btree opclass), whereas it should use the ordering function specified by the GIN opclass, if any. This led to a failure if the data type has no btree opclass, or to an invalid index if the opclass specifies an ordering function that doesn't agree with the btree opclass.

- Prevent truncation of CLOG that is still needed by unread `NOTIFY` messages (Joel Jacobson, Heikki Linnakangas)

This fix prevents “could not access status of transaction” errors when a backend is slow to absorb `NOTIFY` messages.

- Escalate errors occurring during `NOTIFY` message processing to `FATAL`, i.e. close the connection (Heikki Linnakangas)

Formerly, if a backend got an error while absorbing a `NOTIFY` message, it would advance past that message, report the error to the client, and move on. That behavior was fraught with problems though. One big concern is that the client has no good way to know that a notification was lost, and certainly no way to know what was in it. Depending on the application logic, missing a notification could cause the application to get stuck waiting, for example. Also, any remaining messages would not get processed until someone sent a new `NOTIFY`.

Also, if the connection is idle at the time of receiving a `NOTIFY` signal, any `ERROR` would be escalated to `FATAL` anyway, due to unrelated concerns. Therefore, we've chosen to make that happen in all cases, for consistency and to provide a clear signal to the application that it might have missed some notifications.

- Consider grouping expressions when computing a query ID hash (Jian He)

Previously, two queries that were the same except in `GROUP BY` expressions would be merged by `contrib/pg_stat_statements` and other users of query IDs.

- Fix erroneous counting of updates in `EXPLAIN ANALYZE MERGE` with a concurrent update (Dean Rasheed)

This situation led to an incorrect count of “skipped” tuples in `EXPLAIN`'s output, or to an assertion failure in an assert-enabled build.

- Fix bug in following update chain when locking a tuple (Jasper Smit)

This code path neglected to check the xmin of the first new tuple in the update chain, making it possible to lock an unrelated tuple if the original updater aborted and the space was immediately reclaimed by `VACUUM` and then re-used. That could cause unexpected transaction delays or deadlocks. Errors associated with having identified the wrong tuple have also been observed.

- Fix incorrect handling of incremental backups of large tables (Robert Haas, Oleg Tkachenko)

If a table exceeding 1GB (or in general, the installation's segment size) is truncated by `VACUUM` between the base backup and the incremental backup, `pg_combinebackup` could fail with an error about “truncation block length in excess of segment size”. This prevented restoring the incremental backup.

- Fix potential backend process crash at process exit due to trying to release a lock in an already-unmapped shared memory segment (Rahila Syed)

- Fix race condition in async I/O code (Andres Freund)

It was possible for the result code of an asynchronous I/O operation to be overwritten before it was fetched.

- Guard against incorrect truncation of the multixact log after a crash (Heikki Linnakangas)

- Fix possibly mis-encoded result of `pg_stat_get_backend_activity()` (Chao Li)

The shared-memory buffer holding a session's activity string can end with an incomplete multibyte character. Readers are supposed to truncate off any such incomplete character, but this function failed to do so.

- Guard against recursive memory context logging (Fujii Masao)

A constant flow of signals requesting memory context logging could cause recursive execution of the logging code, which in theory could lead to stack overflow.

- Fix memory context usage when reinitializing a parallel execution context (Jakub Wartak, Jeevan Chalke)

This error could result in a crash due to a subsidiary data structure having a shorter lifespan than the parallel context. The problem is not known to be reachable using only core PostgreSQL, but we have reports of trouble in extensions.

- Set next multixid's offset when creating a new multixid, to remove the wait loop that was needed in corner cases (Andrey Borodin)

The previous logic could get stuck waiting for an update that would never occur.

- Avoid rewriting data-modifying CTEs more than once (Bernice Southey, Dean Rasheed)

Formerly, when updating an auto-updatable view or a relation with rules, if the original query had any data-modifying CTEs, the rewriter would rewrite those CTEs multiple times due to recursion. This was inefficient and could produce false errors if a CTE included an update of an always-generated column.

- Allow retrying initialization of a DSM registry entry (Nathan Bossart)

If we fail partway through initialization of a dynamic shared memory entry, allow the next attempt to use that entry to retry initialization. Previously the entry was left in a permanently-failed state.

- Avoid failure of NUMA status views when a page has been swapped out (Tomas Vondra)
- Avoid “operation not permitted” errors when querying NUMA page status with older libnuma versions (Tomas Vondra)
- Fail recovery if WAL does not exist back to the redo point indicated by the checkpoint record (Nitin Jadhav)

Add an explicit check for this before starting recovery, so that no harm is done and a useful error message is provided. Previously, recovery might crash or corrupt the database in this situation.

- Avoid scribbling on the source query tree during `ALTER PUBLICATION` (Sunil S)

This error had the visible effect that an event trigger fired for the query would see only the first `publish` option, even if several had been specified. If such a query were set up as a prepared statement, re-executions would misbehave too.

- Pass connection options specified in `CREATE SUBSCRIPTION . . . CONNECTION` to the publisher's walsender (Fujii Masao)

Before this fix, the `options` connection option (if any) was ignored, thus for example preventing setting custom server parameter values in the walsender session. It was intended for that to work, and it did work before refactoring in PostgreSQL version 15 broke it, so restore the previous behavior.

- Prevent invalidation of newly created or newly synced replication slots (Zhijie Hou)

A race condition with a concurrent checkpoint could allow WAL to be removed that is needed by the replication slot, causing the slot to immediately get marked invalid.

- Fix race condition in computing a replication slot's required xmin (Zhijie Hou)

This could lead to the error “cannot build an initial slot snapshot as oldest safe xid follows snapshot's xmin”.

- During initial synchronization of a logical replication subscription, commit the addition of a `pg_replication_origin` entry before starting to copy data (Zhijie Hou)

Previously, if the copy step failed, the new `pg_replication_origin` entry would be lost due to transaction rollback. This led to inconsistent state in shared memory.

- Don't advance logical replication progress after a parallel worker apply failure (Zhijie Hou)

The previous behavior allowed transactions to be lost by a subscriber.

- Fix logical replication slotsync worker processes to handle `LOCK_TIMEOUT` signals correctly (Zhijie Hou)

Previously, timeout signals were effectively ignored.

- Fix possible failure with “unexpected data beyond EOF” during restart of a streaming replica server (Anthonin Bonnefoy)

- Fix error reporting for SQL/JSON path type mismatches (Jian He)

The code could produce a “cache lookup failed for type 0” error instead of the intended complaint about the path expression not being of the right type.

- Fix erroneous tracking of column position when parsing partition range bounds (myzhen)

This could, for example, lead to the wrong column name being cited in error messages about casting partition bound values to the column's data type.

- Fix assorted minor errors in error messages (Man Zeng, Tianchen Zhang)

For example, an error report about mismatched timeline number in a backup manifest showed the starting timeline number where it meant to show the ending timeline number.

- Fix failure to perform function inlining when doing JIT compilation with LLVM version 17 or later (Anthonin Bonnefoy)

- Adjust our JIT code to work with LLVM 21 (Holger Hoffstätte)

The previous coding failed to compile on aarch64 machines.

- Fix aarch64-specific code to build with old (RHEL7-era) system header files (Tom Lane)

- Fix incorrect configure probe for `io_uring_queue_init_mem()` (Masahiko Sawada)

This error resulted in failure to optimize async I/O buffer allocations in autotools-based builds, though the code did work when building with meson. The main impact of the omission was slower-than-necessary backend process exits.

- Add new server parameter `file_extend_method` to control use of `posix_fallocate()` (Thomas Munro)

PostgreSQL version 16 and later will use `posix_fallocate()`, if the platform provides it, to extend relation files. However, this has been reported to interact poorly with some file systems: BTRFS compression is disabled by the use of `posix_fallocate()`, and XFS could produce spurious `ENOSPC` errors in older Linux kernel versions. To provide a workaround, introduce this new server parameter. Setting `file_extend_method` to `write_zeros` will cause the server to return to the old method of extending files by writing blocks of zeroes.

- Honor `open()`'s `O_CLOEXEC` flag on Windows (Bryan Green, Thomas Munro)

Make this flag work like it does on POSIX platforms, so that we don't leak file handles into child processes such as `COPY TO/FROM PROGRAM`. While that leakage hasn't caused many problems, it seems undesirable.

- Fix failure to parse long options on the server command line in Solaris executables built with meson (Tom Lane)
- Support process title changes on GNU/Hurd (Michael Banck)
- Fix `psql`'s tab completion for `VACUUM` option values (Yugo Nagata)
- In `psql` command prompts, do not show a value for `%P` (pipeline status) when there is no server connection (Chao Li)

This makes `%P` act like other prompt escape sequences whose values depend on the active connection.

- Fix `pg_dump`'s logic for collecting sequence values (Nathan Bossart)

`pg_dump` failed if a sequence was dropped concurrently with the dump, even if the sequence was not among the database objects to be dumped. Also, if the calling user lacks privileges to read a sequence's value, `pg_dump` emitted incorrect values rather than failing as expected.

- Fix potentially-incorrect quoting of `oauth_validator_libraries` values by `pg_dump` (ChangAo Chen)

`pg_dump` applied the wrong quoting rule if it needed to dump a value of this setting.

- Avoid `pg_dump` assertion failure in binary-upgrade mode (Vignesh C)

Failure to handle subscription-relation objects in the object sorting code triggered an assertion, though there were no serious ill effects in production builds.

- Fix incorrect error handling in `pgbench` with multiple `\syncpipeline` commands in pipeline mode (Yugo Nagata)

If multiple `\syncpipeline` commands are encountered after a query error, `pgbench` would report “failed to exit pipeline mode”, or get an assertion failure in an assert-enabled build.

- Make `pg_resetwal` print the updated value when changing `OldestXID` (Heikki Linnakangas)

It already did that for every other variable it can change.

- Make `pg_resetwal` allow setting next multixact xid to 0 or next multixact offset to `UINT32_MAX` (Maxim Orlov)

These are valid values, so rejecting them was incorrect. In the worst case, if a `pg_upgrade` is attempted when exactly at the point of multixact wraparound, the upgrade would fail.

- In `contrib/amcheck`, use the correct snapshot for btree index parent checks (Mihail Nikalayeu)

The previous coding caused spurious errors when examining indexes created with `CREATE INDEX CONCURRENTLY`.

- Fix `contrib/amcheck` to handle “half-dead” btree index pages correctly (Heikki Linnakangas)

`amcheck` expected such a page to have a parent downlink, but it does not, leading to a false error report about “mismatch between parent key and child high key”.

- Fix `contrib/amcheck` to handle incomplete btree root page splits correctly (Heikki Linnakangas)

`amcheck` could report a false error about “block is not true root”.

- Fix excessive memory allocation in `contrib/pg_buffercache` (David Geier)

The code allocated twice as much memory as it needed for NUMA page status.

- Fix edge-case integer overflow in `contrib/intarray`'s selectivity estimator for `@@` (Chao Li)

This could cause poor selectivity estimates to be produced for cases involving the maximum integer value.

- Fix multibyte-encoding issue in `contrib/ltree` (Jeff Davis)

The previous coding could pass an incomplete multibyte character to `lower ( )`, probably resulting in incorrect behavior.

- Avoid crash in `contrib/pg_stat_statements` when an `IN` list contains both constants and non-constant expressions (Sami Imseih)
- Update time zone data files to `tzdata` release 2025c (Tom Lane)

The only change is in historical data for pre-1976 timestamps in Baja California.

## E.4. Release 18.1

**Release date:** 2025-11-13

This release contains a variety of fixes from 18.0. For information about new features in major release 18, see Section E.5.

### E.4.1. Migration to Version 18.1

A dump/restore is not required for those running 18.X.

### E.4.2. Changes

- Check for `CREATE` privileges on the schema in `CREATE STATISTICS` (Jelte Fennema-Nio)

This omission allowed table owners to create statistics in any schema, potentially leading to unexpected naming conflicts.

The PostgreSQL Project thanks Jelte Fennema-Nio for reporting this problem. (CVE-2025-12817)

- Avoid integer overflow in allocation-size calculations within `libpq` (Jacob Champion)

Several places in `libpq` were not sufficiently careful about computing the required size of a memory allocation. Sufficiently large inputs could cause integer overflow, resulting in an undersized buffer, which would then lead to writing past the end of the buffer.

The PostgreSQL Project thanks Aleksey Solovov of Positive Technologies for reporting this problem. (CVE-2025-12818)

- Prevent “unrecognized node type” errors when a SQL/JSON function such as `JSON_VALUE` has a `DEFAULT` clause containing a `COLLATE` expression (Jian He)
- Avoid incorrect optimization of variable-free `HAVING` clauses with grouping sets (Richard Guo)
- Do not use parallelism in hash right semi joins (Richard Guo)

The case does not work reliably due to a race condition in updating the join's shared hash table.

- Avoid possible division-by-zero when creating ordered-append plans (Richard Guo)

This mistake could result in incorrect selection of the cheapest path, or in an assertion failure in debug builds.

- Fix planner failure with index types that can do ordered access but not index-only scans (Maxime Schoemans)

This oversight resulted in errors like “no data returned for index-only scan”. The case does not arise with any in-core index type, but some extensions encountered the problem.

- Remove faulty assertion in btree index cleanup (Peter Geoghegan)
- Avoid possible out-of-memory or “invalid memory alloc request size” failures during parallel GIN index build (Tomas Vondra)
- Ensure that BRIN autosummarization provides a snapshot for index expressions that need one (Álvaro Herrera)

Previously, autosummarization would fail for such indexes, and then leave placeholder index tuples behind, causing the index to bloat over time.

- Fix integer-overflow hazard in BRIN index scans when the table contains close to  $2^{32}$  pages (Sunil S)

This oversight could result in an infinite loop or scanning of unneeded table pages.

- Fix incorrect zero-extension of stored values in JIT-generated tuple deforming code (David Rowley)

When not using JIT, the equivalent code does sign-extension not zero-extension, leading to a different Datum representation of small integer data types. This inconsistency was masked in most cases, but it is known to lead to “could not find memoization table entry” errors when using Memoize plan nodes, and there might be other symptoms.

- Fix rare crash when processing hashed `GROUPING SETS` queries (David Rowley)
- Repair faulty hash-table-size-choosing logic in hash joins (Tomas Vondra)

Hash joins sometimes used more memory than intended, or failed to divide it in an efficient way.

- Improve relation lookup logic in statistics manipulation functions (Nathan Bossart)

Fix `pg_restore_relation_stats()`, `pg_clear_relation_stats()`, `pg_restore_attribute_stats()`, and `pg_clear_attribute_stats()` to check privileges before acquiring lock on the target relation rather than after.

- Fix incorrect logic for caching result-relation information for triggers (David Rowley, Amit Langote)

In cases where partitions' column sets aren't physically identical to their parent partitioned tables' column sets, this oversight could lead to crashes.

- Fix crash during EvalPlanQual rechecks on partitioned tables (David Rowley, Amit Langote)
- Fix EvalPlanQual handling of foreign or custom joins that do not have an alternative local-join plan prepared for EPQ (Masahiko Sawada, Etsuro Fujita)

In such cases the foreign or custom access method should be invoked normally, but that did not happen, typically leading to a crash.

- Avoid duplicating hash partition constraints during `DETACH CONCURRENTLY` (Haiyang Li)

`ALTER TABLE DETACH PARTITION CONCURRENTLY` was written to add a copy of the partitioning constraint to the now-detached partition. This was misguided, partially because non-concurrent `DETACH` doesn't do that, but mostly because in the case of hash partitioning the constraint expression contains references to the parent table's OID. That causes problems during dump/restore,

or if the parent table is dropped after `DETACH`. In v19 and later, we'll no longer create any such copied constraints at all. In released branches, to minimize the risk of unforeseen consequences, only skip adding a copied constraint if it is for hash partitioning.

- Disallow generated columns in partition keys (Jian He, Ashutosh Bapat)

This was already not allowed, but the check missed some cases, such as where the column reference is implicit in a whole-row reference.

- Disallow generated columns in `COPY . . . FROM . . . WHERE` clauses (Peter Eisentraut, Jian He)

Previously, incorrect behavior or an obscure error message resulted from attempting to reference such a column, since generated columns have not yet been computed at the point where `WHERE` filtering is done.

- Prevent setting a column as identity if it has a not-null constraint but the constraint is marked as invalid (Jian He)

Identity columns must be not-null, but the check for that missed this edge case.

- Avoid potential use-after-free in parallel vacuum (Kevin Oommen Anish)

This bug seems to have no consequences in standard builds, but it's theoretically a hazard.

- Fix visibility checking for statistics objects in `pg_temp` (Noah Misch)

A statistics object located in a temporary schema cannot be named without schema qualification, but `pg_statistics_obj_is_visible()` missed that memo and could return “true” regardless. In turn, functions such as `pg_describe_object()` could fail to schema-qualify the object's name as expected.

- Fix minor memory leak during WAL replay of database creation (Nathan Bossart)

- Fix incorrect reporting of replication lag in `pg_stat_replication` view (Fujii Masao)

If any standby server's replay LSN stopped advancing, the `write_lag` and `flush_lag` columns would eventually stop updating.

- Avoid duplicative log messages about invalid `primary_slot_name` settings (Fujii Masao)

- Avoid failures when `synchronized_standby_slots` references nonexistent replication slots (Shlok Kyal)

- Remove the unfinished slot state file after failing to write a replication slot's state to disk (Michael Paquier)

Previously, a failure such as out-of-disk-space resulted in leaving a temporary `state.tmp` file behind. That's problematic because it would block all subsequent attempts to write the state, requiring manual intervention to clean up.

- Fix mishandling of lock timeout signals in parallel apply workers for logical replication (Hayato Kuroda)

The same signal number was being used for both worker shutdown and lock timeout, leading to confusion.

- Avoid unwanted WAL receiver shutdown when switching from streaming to archive WAL source (Xuneng Zhou)

During a timeline change, a standby server's WAL receiver should remain alive, waiting for a new WAL streaming start point. Instead it was repeatedly shutting down and immediately getting restarted, which could confuse status monitoring code.

- Fix use-after-free issue in the relation synchronization cache maintained by the pgoutput logical decoding plugin (Vignesh C, Masahiko Sawada)

An error during logical decoding could result in crashes in subsequent logical decoding attempts in the same session. The case is only reachable when pgoutput is invoked via SQL functions.

- Avoid unnecessary invalidation of logical replication slots (Bertrand Drouvot)
- Re-establish special case for C collation in locale setup (Jeff Davis)

This fixes a regression in access to shared catalogs early in backend startup, before a database has been selected. It is not known to be a problem for any core PostgreSQL code, but some extensions were broken.

- Fix incorrect printing of messages about failures in checking whether the user has Windows administrator privilege (Bryan Green)

This code would have crashed or at least printed garbage. No such cases have been reported though, indicating that failure of these system calls is extremely rare.

- Avoid crash when attempting to test PostgreSQL with certain libsanitizer options (Emmanuel Sibi, Jacob Champion)
- Fix false memory-context-checking warnings in debug builds on 64-bit Windows (David Rowley)
- Correctly handle `GROUP BY DISTINCT` in PL/pgSQL assignment statements (Tom Lane)

The parser failed to record the `DISTINCT` option in this context, so that the command would act as if it were plain `GROUP BY`.

- Avoid leaking memory when handling a SQL error within PL/Python (Tom Lane)

This fixes a session-lifespan memory leak introduced in our previous minor releases.

- Fix libpq's handling of socket-related errors on Windows within its GSSAPI logic (Ning Wu, Tom Lane)

The code for encrypting/decrypting transmitted data using GSSAPI did not correctly recognize error conditions on the connection socket, since Windows reports those differently than other platforms. This led to failure to make such connections on Windows.

- Fix dumping of non-inherited not-null constraints on inherited table columns (Dilip Kumar)

`pg_dump` failed to preserve such constraints when dumping from a pre-v18 server.

- Fix `pg_dump`'s sorting of foreign key constraints (Álvaro Herrera)

Ensure consistent ordering of these database objects, as was already done for other object types.

- Fix assorted errors in the data compression logic in `pg_dump` and `pg_restore` (Daniel Gustafsson, Tom Lane)

Error checking was missing or incorrect in several places, and there were also portability issues that would manifest on big-endian hardware. These problems had been missed because this code is only used to read compressed TOC files within directory-format dumps. `pg_dump` never produces such a dump; the case can be reached only by manually compressing the TOC file after the fact, which is a supported thing to do but very uncommon.

- Fix `pgbench` to error out cleanly if a `COPY` operation is started (Anthonin Bonnefoy)

`pgbench` doesn't intend to support this case, but previously it went into an infinite loop.

- Fix pgbench's reporting of multiple errors (Yugo Nagata)

In cases where two successive `PQgetResult` calls both fail, pgbench might report the wrong error message.

- In pgbench, fix faulty assertion about errors in pipeline mode (Yugo Nagata)
- Fix per-file memory leakage in `pg_combinebackup` (Tom Lane)
- Ensure that `contrib/pg_buffercache` functions can be canceled (Satyanarayana Narlapuram, Yuhang Qiu)

Some code paths were capable of running for a long time without checking for interrupts.

- Fix `contrib/pg_prewarm`'s privilege checks for indexes (Ayush Vatsa, Nathan Bossart)

`pg_prewarm()` requires `SELECT` privilege on relations to be prewarmed. However, since indexes have no SQL privileges of their own, this resulted in non-superusers being unable to prewarm indexes. Instead, check for `SELECT` privilege on the index's table.

- In `contrib/pg_stat_statements`, avoid crash when two or more constants are marked as having the same location in the SQL statement text (Sami Imseih, Dmitry Dolgov)
- Make `contrib/pgstattuple` more robust about empty or invalid index pages (Nitin Motiani)

Count all-zero pages as free space, and ignore pages that are invalid according to a check of the page's special-space size. The code for btree indexes already counted all-zero pages as free, but the hash and gist code would error out, which has been found to be much less user-friendly. Similarly, make all three cases agree on ignoring corrupted pages rather than throwing errors.

- Harden our read and write barrier macros to satisfy Clang (Thomas Munro)

We supposed that `__atomic_thread_fence()` is a sufficient barrier to prevent the C compiler from re-ordering memory accesses around it, but it appears that that's not true for Clang, allowing it to generate incorrect code for at least RISC-V, MIPS, and LoongArch machines. Add explicit compiler barriers to fix that.

- Fix PGXS build infrastructure to support building NLS po files for extensions (Ryo Matsumura)

## E.5. Release 18

**Release date:** 2025-09-25

### E.5.1. Overview

PostgreSQL 18 contains many new features and enhancements, including:

- An asynchronous I/O (AIO) subsystem that can improve performance of sequential scans, bitmap heap scans, vacuums, and other operations.
- `pg_upgrade` now retains optimizer statistics.
- Support for "skip scan" lookups that allow using multicolumn B-tree indexes in more cases.
- `uuidv7()` function for generating timestamp-ordered UUIDs.
- Virtual generated columns that compute their values during read operations. This is now the default for generated columns.
- OAuth authentication support.

- OLD and NEW support for RETURNING clauses in INSERT, UPDATE, DELETE, and MERGE commands.
- Temporal constraints, or constraints over ranges, for PRIMARY KEY, UNIQUE, and FOREIGN KEY constraints.

The above items and other new features of PostgreSQL 18 are explained in more detail in the sections below.

## E.5.2. Migration to Version 18

A dump/restore using `pg_dumpall` or use of `pg_upgrade` or logical replication is required for those wishing to migrate data from any previous release. See Section 18.6 for general information on migrating to new major releases.

Version 18 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change initdb default to enable data checksums (Greg Sabino Mullane)

Checksums can be disabled with the new initdb option `--no-data-checksums`. `pg_upgrade` requires matching cluster checksum settings, so this new option can be useful to upgrade non-checksum old clusters.

- Change time zone abbreviation handling (Tom Lane)

The system will now favor the current session's time zone abbreviations before checking the server variable `timezone_abbreviations`. Previously `timezone_abbreviations` was checked first.

- Deprecate MD5 password authentication (Nathan Bossart)

Support for MD5 passwords will be removed in a future major version release. `CREATE ROLE` and `ALTER ROLE` now emit deprecation warnings when setting MD5 passwords. These warnings can be disabled by setting the `md5_password_warnings` parameter to `off`.

- Change VACUUM and ANALYZE to process the inheritance children of a parent (Michael Harris)

The previous behavior can be performed by using the new `ONLY` option.

- Prevent `COPY FROM` from treating `\.` as an end-of-file marker when reading CSV files (Daniel Vérité, Tom Lane)

`psql` will still treat `\.` as an end-of-file marker when reading CSV files from `STDIN`. Older `psql` clients connecting to PostgreSQL 18 servers might experience `\copy` problems. This release also enforces that `\.` must appear alone on a line.

- Disallow unlogged partitioned tables (Michael Paquier)

Previously `ALTER TABLE SET [UN]LOGGED` did nothing, and the creation of an unlogged partitioned table did not cause its children to be unlogged.

- Execute AFTER triggers as the role that was active when trigger events were queued (Laurenz Albe)

Previously such triggers were run as the role that was active at trigger execution time (e.g., at COMMIT). This is significant for cases where the role is changed between queue time and transaction commit.

- Remove non-functional support for rule privileges in GRANT/REVOKE (Fujii Masao)

These have been non-functional since PostgreSQL 8.2.

- Remove column `pg_backend_memory_contexts.parent` (Melih Mutlu)

This is no longer needed since `pg_backend_memory_contexts.path` was added.

- Change `pg_backend_memory_contexts.level` and `pg_log_backend_memory_contexts()` to be one-based (Melih Mutlu, Atsushi Torikoshi, David Rowley, Fujii Masao)

These were previously zero-based.

- Change full text search to use the default collation provider of the cluster to read configuration files and dictionaries, rather than always using `libc` (Peter Eisentraut)

Clusters that default to non-`libc` collation providers (e.g., ICU, builtin) that behave differently than `libc` for characters processed by `LC_CTYPE` could observe changes in behavior of some full-text search functions, as well as the `pg_trgm` extension. When upgrading such clusters using `pg_upgrade`, it is recommended to reindex all indexes related to full-text search and `pg_trgm` after the upgrade.

## E.5.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 18 and the previous major release.

### E.5.3.1. Server

#### E.5.3.1.1. Optimizer

- Automatically remove some unnecessary table self-joins (Andrey Lepikhov, Alexander Kuzmenkov, Alexander Korotkov, Alena Rybakina)

This optimization can be disabled using server variable `enable_self_join_elimination`.

- Convert some `IN (VALUES ...)` to `x = ANY ...` for better optimizer statistics (Alena Rybakina, Andrei Lepikhov)
- Allow transforming `OR`-clauses to arrays for faster index processing (Alexander Korotkov, Andrey Lepikhov)
- Speed up the processing of `INTERSECT`, `EXCEPT`, window aggregates, and view column aliases (Tom Lane, David Rowley)
- Allow the keys of `SELECT DISTINCT` to be internally reordered to avoid sorting (Richard Guo)

This optimization can be disabled using `enable_distinct_reordering`.

- Ignore `GROUP BY` columns that are functionally dependent on other columns (Zhang Mingli, Jian He, David Rowley)

If a `GROUP BY` clause includes all columns of a unique index, as well as other columns of the same table, those other columns are redundant and can be dropped from the grouping. This was already true for non-deferred primary keys.

- Allow some `HAVING` clauses on `GROUPING SETS` to be pushed to `WHERE` clauses (Richard Guo)

This allows earlier row filtering. This release also fixes some `GROUPING SETS` queries that used to return incorrect results.

- Improve row estimates for `generate_series()` using numeric and timestamp values (David Rowley, Song Jinzhou)
- Allow the optimizer to use `Right Semi Join` plans (Richard Guo)

Semi-joins are used when needing to find if there is at least one match.

- Allow merge joins to use incremental sorts (Richard Guo)
- Improve the efficiency of planning queries accessing many partitions (Ashutosh Bapat, Yuya Watari, David Rowley)
- Allow partitionwise joins in more cases, and reduce its memory usage (Richard Guo, Tom Lane, Ashutosh Bapat)
- Improve cost estimates of partition queries (Nikita Malakhov, Andrei Lepikhov)
- Improve SQL-language function plan caching (Alexander Pyhalov, Tom Lane)
- Improve handling of disabled optimizer features (Robert Haas)

### **E.5.3.1.2. Indexes**

- Allow skip scans of btree indexes (Peter Geoghegan)

This allows multi-column btree indexes to be used in more cases such as when there are no restrictions on the first or early indexed columns (or there are non-equality ones), and there are useful restrictions on later indexed columns.

- Allow non-btree unique indexes to be used as partition keys and in materialized views (Mark Dilger)

The index type must still support equality.

- Allow GIN indexes to be created in parallel (Tomas Vondra, Matthias van de Meent)
- Allow values to be sorted to speed range-type GiST and btree index builds (Bernd Helmle)

### **E.5.3.1.3. General Performance**

- Add an asynchronous I/O subsystem (Andres Freund, Thomas Munro, Nazir Bilal Yavuz, Melanie Plageman)

This feature allows backends to queue multiple read requests, which allows for more efficient sequential scans, bitmap heap scans, vacuums, etc. This is enabled by server variable `io_method`, with server variables `io_combine_limit` and `io_max_combine_limit` added to control it. This also enables `effective_io_concurrency` and `maintenance_io_concurrency` values greater than zero for systems without `fadvise()` support. The new system view `pg_aios` shows the file handles being used for asynchronous I/O.

- Improve the locking performance of queries that access many relations (Tomas Vondra)
- Improve the performance and reduce memory usage of hash joins and `GROUP BY` (David Rowley, Jeff Davis)

This also improves hash set operations used by `EXCEPT`, and hash lookups of subplan values.

- Allow normal vacuums to freeze some pages, even though they are all-visible (Melanie Plageman)

This reduces the overhead of later full-relation freezing. The aggressiveness of this can be controlled by server variable and per-table setting `vacuum_max_eager_freeze_failure_rate`. Previously vacuum never processed all-visible pages until freezing was required.

- Add server variable `vacuum_truncate` to control file truncation during `VACUUM` (Nathan Bossart, Gurjeet Singh)

A storage-level parameter with the same name and behavior already existed.

- Increase server variables `effective_io_concurrency`'s and `maintenance_io_concurrency`'s default values to 16 (Melanie Plageman)

This more accurately reflects modern hardware.

#### E.5.3.1.4. Monitoring

- Increase the logging granularity of server variable `log_connections` (Melanie Plageman)

This server variable was previously only boolean, which is still supported.

- Add `log_connections` option to report the duration of connection stages (Melanie Plageman)
- Add `log_line_prefix` escape `%L` to output the client IP address (Greg Sabino Mullane)
- Add server variable `log_lock_failures` to log lock acquisition failures (Yuki Seino, Fujii Masao)

Specifically it reports `SELECT . . . NOWAIT` lock failures.

- Modify `pg_stat_all_tables` and its variants to report the time spent in `VACUUM`, `ANALYZE`, and their automatic variants (Sami Imseih)

The new columns are `total_vacuum_time`, `total_autovacuum_time`, `total_analyze_time`, and `total_autoanalyze_time`.

- Add delay time reporting to `VACUUM` and `ANALYZE` (Bertrand Drouvot, Nathan Bossart)

This information appears in the server log, the system views `pg_stat_progress_vacuum` and `pg_stat_progress_analyze`, and the output of `VACUUM` and `ANALYZE` when in `VERBOSE` mode; tracking must be enabled with the server variable `track_cost_delay_timing`.

- Add WAL, CPU, and average read statistics output to `ANALYZE VERBOSE` (Anthonin Bonnefoy)
- Add full WAL buffer count to `VACUUM/ANALYZE (VERBOSE)` and autovacuum log output (Bertrand Drouvot)
- Add per-backend I/O statistics reporting (Bertrand Drouvot)

The statistics are accessed via `pg_stat_get_backend_io()`. Per-backend I/O statistics can be cleared via `pg_stat_reset_backend_stats()`.

- Add `pg_stat_io` columns to report I/O activity in bytes (Nazir Bilal Yavuz)

The new columns are `read_bytes`, `write_bytes`, and `extend_bytes`. The `op_bytes` column, which always equaled `BLCKSZ`, has been removed.

- Add WAL I/O activity rows to `pg_stat_io` (Nazir Bilal Yavuz, Bertrand Drouvot, Michael Paquier)

This includes WAL receiver activity and a wait event for such writes.

- Change server variable `track_wal_io_timing` to control tracking WAL timing in `pg_stat_io` instead of `pg_stat_wal` (Bertrand Drouvot)
- Remove read/sync columns from `pg_stat_wal` (Bertrand Drouvot)

This removes columns `wal_write`, `wal_sync`, `wal_write_time`, and `wal_sync_time`.

- Add function `pg_stat_get_backend_wal()` to return per-backend WAL statistics (Bertrand Drouvot)

Per-backend WAL statistics can be cleared via `pg_stat_reset_backend_stats()`.

- Add function `pg_ls_summariesdir()` to specifically list the contents of `PGDATA/pg_wal/summaries` (Yushi Ogiwara)
- Add column `pg_stat_checkpoint.num_done` to report the number of completed checkpoints (Anton A. Melnikov)  
  
Columns `num_timed` and `num_requested` count both completed and skipped checkpoints.
- Add column `pg_stat_checkpointer.slru_written` to report SLRU buffers written (Nitin Jadhav)  
  
Also, modify the checkpoint server log message to report separate shared buffer and SLRU buffer values.
- Add columns to `pg_stat_database` to report parallel worker activity (Benoit Lobréau)  
  
The new columns are `parallel_workers_to_launch` and `parallel_workers_launched`.
- Have query id computation of constant lists consider only the first and last constants (Dmitry Dolgov, Sami Imseih)  
  
Jumbling is used by `pg_stat_statements`.
- Adjust query id computations to group together queries using the same relation name (Michael Paquier, Sami Imseih)  
  
This is true even if the tables in different schemas have different column names.
- Add column `pg_backend_memory_contexts.type` to report the type of memory context (David Rowley)
- Add column `pg_backend_memory_contexts.path` to show memory context parents (Melih Mutlu)

#### **E.5.3.1.5. Privileges**

- Add function `pg_get_acl()` to retrieve database access control details (Joel Jacobson)
- Add function `has_largeobject_privilege()` to check large object privileges (Yugo Nagata)
- Allow `ALTER DEFAULT PRIVILEGES` to define large object default privileges (Takatsuka Haruka, Yugo Nagata, Laurenz Albe)
- Add predefined role `pg_signal_autovacuum_worker` (Kirill Reshke)  
  
This allows sending signals to autovacuum workers.

#### **E.5.3.1.6. Server Configuration**

- Add support for the OAuth authentication method (Jacob Champion, Daniel Gustafsson, Thomas Munro)  
  
This adds an `oauth` authentication method to `pg_hba.conf`, libpq OAuth options, a server variable `oauth_validator_libraries` to load token validation libraries, and a configure flag `--with-libcurl` to add the required compile-time libraries.
- Add server variable `ssl_tls13_ciphers` to allow specification of multiple colon-separated TLSv1.3 cipher suites (Erica Zhang, Daniel Gustafsson)
- Change server variable `ssl_groups`'s default to include elliptic curve X25519 (Daniel Gustafsson, Jacob Champion)

- Rename server variable `ssl_ecdh_curve` to `ssl_groups` and allow multiple colon-separated ECDH curves to be specified (Erica Zhang, Daniel Gustafsson)

The previous name still works.

- Make cancel request keys 256 bits (Heikki Linnakangas, Jelte Fennema-Nio)

This is only possible when the server and client support wire protocol version 3.2, introduced in this release.

- Add server variable `autovacuum_worker_slots` to specify the maximum number of background workers (Nathan Bossart)

With this variable set, `autovacuum_max_workers` can be adjusted at runtime up to this maximum without a server restart.

- Allow specification of the fixed number of dead tuples that will trigger an autovacuum (Nathan Bossart, Frédéric Yhuel)

The server variable is `autovacuum_vacuum_max_threshold`. Percentages are still used for triggering.

- Change server variable `max_files_per_process` to limit only files opened by a backend (Andres Freund)

Previously files opened by the postmaster were also counted toward this limit.

- Add server variable `num_os_semaphores` to report the required number of semaphores (Nathan Bossart)

This is useful for operating system configuration.

- Add server variable `extension_control_path` to specify the location of extension control files (Peter Eisentraut, Matheus Alcantara)

### E.5.3.1.7. Streaming Replication and Recovery

- Allow inactive replication slots to be automatically invalidated using server variable `idle_replication_slot_timeout` (Nisha Moond, Bharath Rupireddy)
- Add server variable `max_active_replication_origins` to control the maximum active replication origins (Euler Taveira)

This was previously controlled by `max_replication_slots`, but this new setting allows a higher origin count in cases where fewer slots are required.

### E.5.3.1.8. Logical Replication

- Allow the values of generated columns to be logically replicated (Shubham Khanna, Vignesh C, Zhijie Hou, Shlok Kyal, Peter Smith)

If the publication specifies a column list, all specified columns, generated and non-generated, are published. Without a specified column list, publication option `publish_generated_columns` controls whether generated columns are published. Previously generated columns were not replicated and the subscriber had to compute the values if possible; this is particularly useful for non-PostgreSQL subscribers which lack such a capability.

- Change the default `CREATE SUBSCRIPTION` streaming option from `off` to `parallel` (Vignesh C)
- Allow `ALTER SUBSCRIPTION` to change the replication slot's two-phase commit behavior (Hayato Kuroda, Ajin Cherian, Amit Kapila, Zhijie Hou)

- Log conflicts while applying logical replication changes (Zhijie Hou, Nisha Moond)

Also report in new columns of `pg_stat_subscription_stats`.

### E.5.3.2. Utility Commands

- Allow generated columns to be virtual, and make them the default (Peter Eisentraut, Jian He, Richard Guo, Dean Rasheed)

Virtual generated columns generate their values when the columns are read, not written. The write behavior can still be specified via the `STORED` option.

- Add `OLD/NEW` support to `RETURNING` in DML queries (Dean Rasheed)

Previously `RETURNING` only returned new values for `INSERT` and `UPDATE`, and old values for `DELETE`; `MERGE` would return the appropriate value for the internal query executed. This new syntax allows the `RETURNING` list of `INSERT/UPDATE/DELETE/MERGE` to explicitly return old and new values by using the special aliases `old` and `new`. These aliases can be renamed to avoid identifier conflicts.

- Allow foreign tables to be created like existing local tables (Zhang Mingli)

The syntax is `CREATE FOREIGN TABLE ... LIKE`.

- Allow `LIKE` with nondeterministic collations (Peter Eisentraut)
- Allow text position search functions with nondeterministic collations (Peter Eisentraut)

These used to generate an error.

- Add builtin collation provider `PG_UNICODE_FAST` (Jeff Davis)

This locale supports case mapping, but sorts in code point order, not natural language order.

- Allow `VACUUM` and `ANALYZE` to process partitioned tables without processing their children (Michael Harris)

This is enabled with the new `ONLY` option. This is useful since autovacuum does not process partitioned tables, just its children.

- Add functions to modify per-relation and per-column optimizer statistics (Corey Huinker)

The functions are `pg_restore_relation_stats()`, `pg_restore_attribute_stats()`, `pg_clear_relation_stats()`, and `pg_clear_attribute_stats()`.

- Add server variable `file_copy_method` to control the file copying method (Nazir Bilal Yavuz)

This controls whether `CREATE DATABASE ... STRATEGY=FILE_COPY` and `ALTER DATABASE ... SET TABLESPACE` uses file copy or clone.

#### E.5.3.2.1. Constraints

- Allow the specification of non-overlapping `PRIMARY KEY`, `UNIQUE`, and foreign key constraints (Paul A. Jungwirth)

This is specified by `WITHOUT OVERLAPS` for `PRIMARY KEY` and `UNIQUE`, and by `PERIOD` for foreign keys, all applied to the last specified column.

- Allow `CHECK` and foreign key constraints to be specified as `NOT ENFORCED` (Amul Sul)

This also adds column `pg_constraint.conenforced`.

- Require primary/foreign key relationships to use either deterministic collations or the the same nondeterministic collations (Peter Eisentraut)

The restore of a `pg_dump`, also used by `pg_upgrade`, will fail if these requirements are not met; schema changes must be made for these upgrade methods to succeed.

- Store column `NOT NULL` specifications in `pg_constraint` (Álvaro Herrera, Bernd Helmle)

This allows names to be specified for `NOT NULL` constraint. This also adds `NOT NULL` constraints to foreign tables and `NOT NULL` inheritance control to local tables.

- Allow `ALTER TABLE` to set the `NOT VALID` attribute of `NOT NULL` constraints (Rushabh Lathia, Jian He)
- Allow modification of the inheritability of `NOT NULL` constraints (Suraj Kharage, Álvaro Herrera)

The syntax is `ALTER TABLE ... ALTER CONSTRAINT ... [NO] INHERIT`.

- Allow `NOT VALID` foreign key constraints on partitioned tables (Amul Sul)
- Allow dropping of constraints `ONLY` on partitioned tables (Álvaro Herrera)

This was previously erroneously prohibited.

#### **E.5.3.2.2. COPY**

- Add `REJECT_LIMIT` to control the number of invalid rows `COPY FROM` can ignore (Atsushi Torikoshi)

This is available when `ON_ERROR = 'ignore'`.

- Allow `COPY TO` to copy rows from populated materialized views (Jian He)
- Add `COPY LOG_VERBOSE` level `silent` to suppress log output of ignored rows (Atsushi Torikoshi)

This new level suppresses output for discarded input rows when `on_error = 'ignore'`.

- Disallow `COPY FREEZE` on foreign tables (Nathan Bossart)

Previously, the `COPY` worked but the `FREEZE` was ignored, so disallow this command.

#### **E.5.3.2.3. EXPLAIN**

- Automatically include `BUFFERS` output in `EXPLAIN ANALYZE` (Guillaume Lelarge, David Rowley)
- Add full WAL buffer count to `EXPLAIN (WAL)` output (Bertrand Drouvot)
- In `EXPLAIN ANALYZE`, report the number of index lookups used per index scan node (Peter Geoghegan)
- Modify `EXPLAIN` to output fractional row counts (Ibrar Ahmed, Ilia Evdokimov, Robert Haas)
- Add memory and disk usage details to `Material`, `Window Aggregate`, and common table expression nodes to `EXPLAIN` output (David Rowley, Tatsuo Ishii)
- Add details about window function arguments to `EXPLAIN` output (Tom Lane)
- Add `Parallel Bitmap Heap Scan` worker cache statistics to `EXPLAIN ANALYZE` (David Geier, Heikki Linnakangas, Donghang Lin, Alena Rybakina, David Rowley)

- Indicate disabled nodes in `EXPLAIN ANALYZE` output (Robert Haas, David Rowley, Laurenz Albe)

### E.5.3.3. Data Types

- Improve Unicode full case mapping and conversion (Jeff Davis)

This adds the ability to do conditional and title case mapping, and case map single characters to multiple characters.

- Allow `jsonb null` values to be cast to scalar types as `NULL` (Tom Lane)

Previously such casts generated an error.

- Add optional parameter to `json{b}_strip_nulls` to allow removal of null array elements (Florents Tselai)
- Add function `array_sort()` which sorts an array's first dimension (Junwang Zhao, Jian He)
- Add function `array_reverse()` which reverses an array's first dimension (Aleksander Alekseev)
- Add function `reverse()` to reverse `bytea` bytes (Aleksander Alekseev)
- Allow casting between integer types and `bytea` (Aleksander Alekseev)

The integer values are stored as `bytea` two's complement values.

- Update Unicode data to Unicode 16.0.0 (Peter Eisentraut)
- Add full text search stemming for Estonian (Tom Lane)
- Improve the XML error codes to more closely match the SQL standard (Tom Lane)

These errors are reported via `SQLSTATE`.

### E.5.3.4. Functions

- Add function `casefold()` to allow for more sophisticated case-insensitive matching (Jeff Davis)

This allows more accurate comparisons, i.e., a character can have multiple upper or lower case equivalents, or upper or lower case conversion changes the number of characters.

- Allow `MIN()`/`MAX()` aggregates on arrays and composite types (Aleksander Alekseev, Marat Buharov)
- Add a `WEEK` option to `EXTRACT()` (Tom Lane)
- Improve the output `EXTRACT(QUARTER ...)` for negative values (Tom Lane)
- Add roman numeral support to `to_number()` (Hunaid Sohail)

This is accessed via the `RN` pattern.

- Add `UUID` version 7 generation function `uuidv7()` (Andrey Borodin)

This `UUID` value is temporally sortable. Function alias `uuidv4()` has been added to explicitly generate version 4 `UUIDs`.

- Add functions `crc32()` and `crc32c()` to compute CRC values (Aleksander Alekseev)
- Add math functions `gamma()` and `lgamma()` (Dean Rasheed)

- Allow `=>` syntax for named cursor arguments in PL/pgSQL (Pavel Stehule)

We previously only accepted `:=`.

- Allow `regexp_match[es]()/regexp_like()/regexp_replace()/regexp_count()/regexp_instr()/regexp_substr()/regexp_split_to_table()/regexp_split_to_array()` to use named arguments (Jian He)

### E.5.3.5. Libpq

- Add function `PQfullProtocolVersion()` to report the full, including minor, protocol version number (Jacob Champion, Jelte Fennema-Nio)
- Add libpq connection parameters and environment variables to specify the minimum and maximum acceptable protocol version for connections (Jelte Fennema-Nio)
- Report `search_path` changes to the client (Alexander Kukushkin, Jelte Fennema-Nio, Tomas Vondra)
- Add `PQtrace()` output for all message types, including authentication (Jelte Fennema-Nio)
- Add libpq connection parameter `sslkeylogfile` which dumps out SSL key material (Abhishek Chanda, Daniel Gustafsson)

This is useful for debugging.

- Modify some libpq function signatures to use `int64_t` (Thomas Munro)

These previously used `pg_int64`, which is now deprecated.

### E.5.3.6. psql

- Allow psql to parse, bind, and close named prepared statements (Anthonin Bonnefoy, Michael Paquier)

This is accomplished with new commands `\parse`, `\bind_named`, and `\close_prepared`.

- Add psql backslash commands to allowing issuance of pipeline queries (Anthonin Bonnefoy)

The new commands are `\startpipeline`, `\syncpipeline`, `\sendpipeline`, `\endpipeline`, `\flushrequest`, `\flush`, and `\getresults`.

- Allow adding pipeline status to the psql prompt and add related state variables (Anthonin Bonnefoy)

The new prompt character is `%P` and the new psql variables are `PIPELINE_SYNC_COUNT`, `PIPELINE_COMMAND_COUNT`, and `PIPELINE_RESULT_COUNT`.

- Allow adding the connection service name to the psql prompt or access it via psql variable (Michael Banck)

- Add psql option to use expanded mode on all list commands (Dean Rasheed)

Adding backslash suffix `x` enables this.

- Change psql's `\conninfo` to use tabular format and include more information (Álvaro Herrera, Maiquel Grassi, Hunaid Sohail)

- Add function's leakproof indicator to psql's `\df+`, `\do+`, `\dAo+`, and `\dC+` outputs (Yugo Nagata)

- Add access method details for partitioned relations in `\dP+` (Justin Pryzby)

- Add `default_version` to the psql `\dx` extension output (Magnus Hagander)

- Add `psql` variable `WATCH_INTERVAL` to set the default `\watch` wait time (Daniel Gustafsson)

### E.5.3.7. Server Applications

- Change `initdb` to default to enabling checksums (Greg Sabino Mullane)  
The new `initdb` option `--no-data-checksums` disables checksums.
- Add `initdb` option `--no-sync-data-files` to avoid syncing heap/index files (Nathan Bossart)  
`initdb` option `--no-sync` is still available to avoid syncing any files.
- Add `vacuumdb` option `--missing-stats-only` to compute only missing optimizer statistics (Corey Huinker, Nathan Bossart)  
This option can only be run by superusers and can only be used with options `--analyze-only` and `--analyze-in-stages`.
- Add `pg_combinebackup` option `-k/--link` to enable hard linking (Israel Barth Rubio, Robert Haas)  
Only some files can be hard linked. This should not be used if the backups will be used independently.
- Allow `pg_verifybackup` to verify tar-format backups (Amul Sul)
- If `pg_rewind`'s `--source-server` specifies a database name, use it in `--write-recovery-conf` output (Masahiko Sawada)
- Add `pg_resetwal` option `--char-signedness` to change the default `char` signedness (Masahiko Sawada)

#### E.5.3.7.1. `pg_dump/pg_dumpall/pg_restore`

- Add `pg_dump` option `--statistics` (Jeff Davis)
- Add `pg_dump` and `pg_dumpall` option `--sequence-data` to dump sequence data that would normally be excluded (Nathan Bossart)
- Add `pg_dump`, `pg_dumpall`, and `pg_restore` options `--statistics-only`, `--no-statistics`, `--no-data`, and `--no-schema` (Corey Huinker, Jeff Davis)
- Add option `--no-policies` to disable row level security policy processing in `pg_dump`, `pg_dumpall`, `pg_restore` (Nikolay Samokhvalov)

This is useful for migrating to systems with different policies.

#### E.5.3.7.2. `pg_upgrade`

- Allow `pg_upgrade` to preserve optimizer statistics (Corey Huinker, Jeff Davis, Nathan Bossart)  
Extended statistics are not preserved. Also add `pg_upgrade` option `--no-statistics` to disable statistics preservation.
- Allow `pg_upgrade` to process database checks in parallel (Nathan Bossart)  
This is controlled by the existing `--jobs` option.
- Add `pg_upgrade` option `--swap` to swap directories rather than copy, clone, or link files (Nathan Bossart)

This mode is potentially the fastest.

- Add `pg_upgrade` option `--set-char-signedness` to set the default `char` signedness of new cluster (Masahiko Sawada)

This is to handle cases where a pre-PostgreSQL 18 cluster's default CPU signedness does not match the new cluster.

### E.5.3.7.3. Logical Replication Applications

- Add `pg_createsubscriber` option `--all` to create logical replicas for all databases (Shubham Khanna)
- Add `pg_createsubscriber` option `--clean` to remove publications (Shubham Khanna)
- Add `pg_createsubscriber` option `--enable-two-phase` to enable prepared transactions (Shubham Khanna)
- Add `pg_recvlogical` option `--enable-failover` to specify failover slots (Hayato Kuroda)

Also add option `--enable-two-phase` as a synonym for `--two-phase`, and deprecate the latter.

- Allow `pg_recvlogical --drop-slot` to work without `--dbname` (Hayato Kuroda)

### E.5.3.8. Source Code

- Separate the loading and running of injection points (Michael Paquier, Heikki Linnakangas)  
  
Injection points can now be created, but not run, via `INJECTION_POINT_LOAD()`, and such injection points can be run via `INJECTION_POINT_CACHED()`.
- Support runtime arguments in injection points (Michael Paquier)
- Allow inline injection point test code with `IS_INJECTION_POINT_ATTACHED()` (Heikki Linnakangas)
- Improve the performance of processing long JSON strings using SIMD (Single Instruction Multiple Data) (David Rowley)
- Speed up CRC32C calculations using x86 AVX-512 instructions (Raghuvveer Devulapalli, Paul Amonson)
- Add ARM Neon and SVE CPU intrinsics for popcount (integer bit counting) (Chiranmoy Bhattacharya, Devanga Susmitha, Rama Malladi)
- Improve the speed of numeric multiplication and division (Joel Jacobson, Dean Rasheed)
- Add configure option `--with-libnuma` to enable NUMA awareness (Jakub Wartak, Bertrand Drouvot)

The function `pg_numa_available()` reports on NUMA awareness, and system views `pg_shmem_allocations_numa` and `pg_buffercache_numa` which report on shared memory distribution across NUMA nodes.

- Add TOAST table to `pg_index` to allow for very large expression indexes (Nathan Bossart)
- Remove column `pg_attribute.attcacheoff` (David Rowley)
- Add column `pg_class.relallfrozen` (Melanie Plageman)
- Add `amgettreeheight`, `amconsistentequality`, and `amconsistentordering` to the index access method API (Mark Dilger)

- Add GiST support function `stratnum()` (Paul A. Jungwirth)
- Record the default CPU signedness of `char` in `pg_controldata` (Masahiko Sawada)
- Add support for Python "Limited API" in PL/Python (Peter Eisentraut)  
This helps prevent problems caused by Python 3.x version mismatches.
- Change the minimum supported Python version to 3.6.8 (Jacob Champion)
- Remove support for OpenSSL versions older than 1.1.1 (Daniel Gustafsson)
- If LLVM is enabled, require version 14 or later (Thomas Munro)
- Add macro `PG_MODULE_MAGIC_EXT` to allow extensions to report their name and version (Andrei Lepikhov)

This information can be access via the new function `pg_get_loaded_modules()`.

- Document that `SPI_connect()/SPI_connect_ext()` always returns success (`SPI_OK_CONNECT`) (Stepan Neretin)

Errors are always reported via `ereport()`.

- Add documentation section about API and ABI compatibility (David Wheeler, Peter Eisentraut)
- Remove the experimental designation of Meson builds on Windows (Aleksander Alekseev)
- Remove configure options `--disable-spinlocks` and `--disable-atomics` (Thomas Munro)

Thirty-two-bit atomic operations are now required.

- Remove support for the HPPA/PA-RISC architecture (Tom Lane)

### E.5.3.9. Additional Modules

- Add extension `pg_logicalinspect` to inspect logical snapshots (Bertrand Drouvot)
- Add extension `pg_overexplain` which adds debug details to `EXPLAIN` output (Robert Haas)
- Add output columns to `postgres_fdw_get_connections()` (Hayato Kuroda, Sagar Dilip Shedge)

New output column `used_in_xact` indicates if the foreign data wrapper is being used by a current transaction, `closed` indicates if it is closed, `user_name` indicates the user name, and `remote_backend_pid` indicates the remote backend process identifier.

- Allow SCRAM authentication from the client to be passed to `postgres_fdw` servers (Matheus Alcantara, Peter Eisentraut)

This avoids storing `postgres_fdw` authentication information in the database, and is enabled with the `postgres_fdw use_scram_passthrough` connection option. `libpq` uses new connection parameters `scram_client_key` and `scram_server_key`.

- Allow SCRAM authentication from the client to be passed to `dblink` servers (Matheus Alcantara)
- Add `on_error` and `log_verbosity` options to `file_fdw` (Atsushi Torikoshi)

These control how `file_fdw` handles and reports invalid file rows.

- Add `reject_limit` to control the number of invalid rows `file_fdw` can ignore (Atsushi Torikoshi)

This is active when `ON_ERROR = 'ignore'`.

- Add configurable variable `min_password_length` to passwordcheck (Emanuele Musella, Maurizio Boriani)

This controls the minimum password length.

- Have `pgbench` report the number of failed, retried, or skipped transactions in per-script reports (Yugo Nagata)
- Add isn server variable `weak` to control invalid check digit acceptance (Viktor Holmberg)

This was previously only controlled by function `isn_weak()`.

- Allow values to be sorted to speed `btree_gist` index builds (Bernd Helmle, Andrey Borodin)
- Add `amcheck` check function `gin_index_check()` to verify GIN indexes (Grigory Kryachko, Heikki Linnakangas, Andrey Borodin)
- Add functions `pg_buffercache_evict_relation()` and `pg_buffercache_evict_all()` to evict unpinned shared buffers (Nazir Bilal Yavuz)

The existing function `pg_buffercache_evict()` now returns the buffer flush status.

- Allow extensions to install custom EXPLAIN options (Robert Haas, Sami Imseih)
- Allow extensions to use the server's cumulative statistics API (Michael Paquier)

#### E.5.3.9.1. `pg_stat_statements`

- Allow the queries of `CREATE TABLE AS` and `DECLARE` to be tracked by `pg_stat_statements` (Anthonin Bonnefoy)

They are also now assigned query ids.

- Allow the parameterization of `SET` values in `pg_stat_statements` (Greg Sabino Mullane, Michael Paquier)

This reduces the bloat caused by `SET` statements with differing constants.

- Add `pg_stat_statements` columns to report parallel activity (Guillaume Lelarge)

The new columns are `parallel_workers_to_launch` and `parallel_workers_launched`.

- Add `pg_stat_statements.wal_buffers_full` to report full WAL buffers (Bertrand Drouvot)

#### E.5.3.9.2. `pgcrypto`

- Add `pgcrypto` algorithms `sha256crypt` and `sha512crypt` (Bernd Helmle)
- Add CFB mode to `pgcrypto` encryption and decryption (Umar Hayat)
- Add function `fips_mode()` to report the server's FIPS mode (Daniel Gustafsson)
- Add `pgcrypto` server variable `builtin_crypto_enabled` to allow disabling builtin non-FIPS mode cryptographic functions (Daniel Gustafsson, Joe Conway)

This is useful for guaranteeing FIPS mode behavior.

# Appendix F. Additional Supplied Modules and Extensions

This appendix and the next one contain information on the optional components found in the `contrib` directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in module libraries found in `contrib`. Appendix G covers utility programs.

When building from the source distribution, these optional components are not built automatically, unless you build the "world" target (see Step 2). You can build and install all of them by running:

**make**  
**make install**

in the `contrib` directory of a configured source tree; or to build and install just one selected module, do the same in that module's subdirectory. Many of the modules have regression tests, which can be executed by running:

**make check**

before installation or

**make installcheck**

once you have a PostgreSQL server running.

If you are using a pre-packaged version of PostgreSQL, these components are typically made available as a separate subpackage, such as `postgresql-contrib`.

Many components supply new user-defined functions, operators, or types, packaged as *extensions*. To make use of one of these extensions, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a `CREATE EXTENSION` command. In a fresh database, you can simply do

```
CREATE EXTENSION extension_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in every database in which you want the extension's facilities to be available. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all extensions, the `CREATE EXTENSION` command must be run by a database superuser, unless the extension is considered "trusted". Trusted extensions can be run by any user who has `CREATE` privilege on the current database. Extensions that are trusted are identified as such in the sections that follow. Generally, trusted extensions are ones that cannot provide access to outside-the-database functionality.

The following extensions are trusted in a default installation:

|                         |                            |                       |                              |
|-------------------------|----------------------------|-----------------------|------------------------------|
| <code>btree_gin</code>  | <code>fuzzystrmatch</code> | <code>ltree</code>    | <code>tcn</code>             |
| <code>btree_gist</code> | <code>hstore</code>        | <code>pgcrypto</code> | <code>tsm_system_rows</code> |

Additional Supplied  
Modules and Extensions

---

|          |          |           |                 |
|----------|----------|-----------|-----------------|
| citext   | intarray | pg_trgm   | tsm_system_time |
| cube     | isn      | seg       | unaccent        |
| dict_int | lo       | tablefunc | uuid-oss        |

Many extensions allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these components are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of `shared_preload_libraries`. See the documentation of each component for details.

## F.1. amcheck — tools to verify table and index consistency

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised. While these checking functions are run, the `search_path` is temporarily changed to `pg_catalog, pg_temp`.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See Section 36.16.3 for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function `verify_heapam` checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that `verify_heapam` relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute `amcheck` functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

### F.1.1. Functions

`bt_index_check(index regclass, heapallindexed boolean, checkunique boolean)` returns `void`

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed =>
      i.indisunique),
      c.relname,
      c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
```

| bt_index_check | relname                         | relpages |
|----------------|---------------------------------|----------|
|                | pg_depend_reference_index       | 43       |
|                | pg_depend_depender_index        | 40       |
|                | pg_proc_prname_args_nsp_index   | 31       |
|                | pg_description_o_c_o_index      | 21       |
|                | pg_attribute_relid_attnam_index | 14       |
|                | pg_proc_oid_index               | 10       |
|                | pg_attribute_relid_attnum_index | 9        |
|                | pg_amproc_fam_proc_index        | 5        |
|                | pg_amop_opr_fam_index           | 5        |
|                | pg_amop_fam_strat_index         | 5        |

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when *heapallindexed* is true. When *checkunique* is true `bt_index_check` will check that no more than one among duplicate entries in unique index is visible. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean, checkunique boolean)` returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *heapallindexed* argument is true, the function verifies the presence of all heap tuples that should be found within the index. When *checkunique* is true `bt_index_parent_check` will check that no more than one among duplicate entries in unique index is visible. When the optional *rootdescend* argument is true, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

`gin_index_check(index regclass)` returns void

`gin_index_check` tests that its target GIN index has consistent parent-child tuples relations (no parent tuples require tuple adjustment) and page graph respects balanced-tree invariants (internal pages reference only leaf page or only internal pages).

### Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive `psql` session before running a verification query will display messages about the progress of verification with a manageable level of detail.

`verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip text, startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT integer, msg OUT text)` returns setof record

Checks a table, sequence, or materialized view for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

**on\_error\_stop**

If true, corruption checking stops at the end of the first block in which any corruptions are found.

Defaults to false.

**check\_toast**

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

**skip**

If not `none`, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are `all-visible`, `all-frozen` and `none`.

Defaults to `none`.

**startblock**

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a *startblock* outside the range of blocks in the target table.

By default, checking begins at the first block.

**endblock**

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an *endblock* outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

**blkno**

The number of the block containing the corrupt page.

**offnum**

The OffsetNumber of the corrupt tuple.

**attnum**

The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

**msg**

A message describing the problem detected.

## F.1.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX CONCURRENTLY` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

## F.1.3. Using `amcheck` Effectively

`amcheck` can be effective at detecting various types of failure modes that data checksums will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used

for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See Section 23.1 and Section 23.2 for further details about how PostgreSQL uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying PostgreSQL access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed PostgreSQL features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests. See Section 31.1 for details on running the tests.

- File system or storage subsystem faults when data checksums are disabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

PostgreSQL does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with data page checksums.

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been de-

signed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to catalog tables is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

## F.1.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

## F.2. `auth_delay` — pause on authentication failure

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via `shared_preload_libraries` in `postgresql.conf`.

### F.2.1. Configuration Parameters

`auth_delay.milliseconds` (integer)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

### F.2.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

## F.3. auto\_explain — log execution plans of slow queries

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

### F.3.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration(integer)`

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_parameter_max_length(integer)`

`auto_explain.log_parameter_max_length` controls the logging of query parameter values. A value of -1 (the default) logs the parameter values in full. 0 disables logging of parameter values. A value greater than zero truncates each parameter value to that many bytes. Only superusers can change this setting.

`auto_explain.log_analyze(boolean)`

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

#### Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers(boolean)`

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has

no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

#### `auto_explain.log_wal` (boolean)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

#### `auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

#### `auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

#### `auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

#### `auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

#### `auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

#### `auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

#### `auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

#### `auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

## F.3.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 3.651 ms  plan:
       Query Text: SELECT count(*)
                   FROM pg_class, pg_index
                   WHERE oid = indrelid AND indisunique;
       Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual
time=3.626..3.627 rows=1.00 loops=1)
         -> Hash Join (cost=4.17..16.55 rows=92 width=0) (actual
time=3.349..3.594 rows=92.00 loops=1)
           Hash Cond: (pg_class.oid = pg_index.indrelid)
             -> Seq Scan on pg_class (cost=0.00..9.55 rows=255
width=4) (actual time=0.016..0.140 rows=255.00 loops=1)
               -> Hash (cost=3.02..3.02 rows=92 width=4) (actual
time=3.238..3.238 rows=92.00 loops=1)
                 Buckets: 1024  Batches: 1  Memory Usage: 4kB
                 -> Seq Scan on pg_index (cost=0.00..3.02 rows=92
width=4) (actual time=0.008..3.187 rows=92.00 loops=1)
                   Filter: indisunique
```

## F.3.3. Author

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>

## F.4. basebackup\_to\_shell — example "shell" pg\_basebackup module

`basebackup_to_shell` adds a custom basebackup target called `shell`. This makes it possible to run `pg_basebackup --target=shell` or, depending on how this module is configured, `pg_basebackup --target=shell:DETAIL_STRING`, and cause a server command chosen by the server administrator to be executed for each tar archive generated by the backup process. The command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create new backup targets via an extension module, but in some scenarios it may be useful for its own sake. In order to function, this module must be loaded via `shared_preload_libraries` or `local_preload_libraries`.

### F.4.1. Configuration Parameters

`basebackup_to_shell.command(string)`

The command which the server should execute for each archive generated by the backup process. If `%f` occurs in the command string, it will be replaced by the name of the archive (e.g. `base.tar`). If `%d` occurs in the command string, it will be replaced by the target detail provided by the user. A target detail is required if `%d` is used in the command string, and prohibited otherwise. For security reasons, it may contain only alphanumeric characters. If `%%` occurs in the command string, it will be replaced by a single `%`. If `%` occurs in the command string followed by any other character or at the end of the string, an error occurs.

`basebackup_to_shell.required_role(string)`

The role required in order to make use of the `shell` backup target. If this is not set, any replication user may make use of the `shell` backup target.

### F.4.2. Author

Robert Haas <[rhaas@postgresql.org](mailto:rhaas@postgresql.org)>

## F.5. `basic_archive` — an example WAL archive module

`basic_archive` is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see Chapter 49.

In order to function, this module must be loaded via `archive_library`, and `archive_mode` must be enabled.

### F.5.1. Configuration Parameters

`basic_archive.archive_directory(string)`

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if `archive_mode` is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```

### F.5.2. Notes

Server crashes may leave temporary files with the prefix `archtemp` in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

### F.5.3. Author

Nathan Bossart

## F.6. bloom — bloom filter index access method

`bloom` provides an index access method based on Bloom filters<sup>1</sup>.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

### F.6.1. Parameters

A `bloom` index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 – col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

### F.6.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
      WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
  SELECT
    (random() * 1000000)::int as i1,
```

---

<sup>1</sup> [https://en.wikipedia.org/wiki/Bloom\\_filter](https://en.wikipedia.org/wiki/Bloom_filter)

```
        (random() * 1000000)::int as i2,  
        (random() * 1000000)::int as i3,  
        (random() * 1000000)::int as i4,  
        (random() * 1000000)::int as i5,  
        (random() * 1000000)::int as i6  
FROM  
  generate_series(1,10000000);  
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =  
123451;
```

QUERY PLAN

```
-----  
Seq Scan on tbloom (cost=0.00..213744.00 rows=250 width=24)  
(actual time=357.059..357.059 rows=0.00 loops=1)  
  Filter: ((i2 = 898732) AND (i5 = 123451))  
    Rows Removed by Filter: 10000000  
    Buffers: shared hit=63744  
Planning Time: 0.346 ms  
Execution Time: 357.076 ms  
(6 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);  
CREATE INDEX  
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));  
pg_size_pretty  
-----  
386 MB  
(1 row)  
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =  
123451;
```

QUERY PLAN

```
-----  
Seq Scan on tbloom (cost=0.00..213744.00 rows=2 width=24) (actual  
time=351.016..351.017 rows=0.00 loops=1)  
  Filter: ((i2 = 898732) AND (i5 = 123451))  
    Rows Removed by Filter: 10000000  
    Buffers: shared hit=63744  
Planning Time: 0.138 ms  
Execution Time: 351.035 ms  
(6 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5,  
i6);  
CREATE INDEX  
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));  
pg_size_pretty  
-----
```

```
153 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =
123451;

                                QUERY PLAN
-----
Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2
width=24) (actual time=22.605..22.606 rows=0.00 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 2300
  Heap Blocks: exact=2256
  Buffers: shared hit=21864
    -> Bitmap Index Scan on bloomidx  (cost=0.00..178436.00 rows=1
width=0) (actual time=20.005..20.005 rows=2300.00 loops=1)
      Index Cond: ((i2 = 898732) AND (i5 = 123451))
      Index Searches: 1
      Buffers: shared hit=19608
Planning Time: 0.099 ms
Execution Time: 22.632 ms
(11 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 =
123451;

                                QUERY PLAN
-----
Bitmap Heap Scan on tbloom  (cost=9.29..13.30 rows=1 width=24)
(actual time=0.032..0.033 rows=0.00 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
  Buffers: shared read=6
    -> BitmapAnd  (cost=9.29..9.29 rows=1 width=0) (actual
time=0.047..0.047 rows=0.00 loops=1)
      Buffers: shared hit=6
        -> Bitmap Index Scan on btreeidx5  (cost=0.00..4.52
rows=11 width=0) (actual time=0.026..0.026 rows=7.00 loops=1)
          Index Cond: (i5 = 123451)
          Index Searches: 1
          Buffers: shared hit=3
        -> Bitmap Index Scan on btreeidx2  (cost=0.00..4.52
rows=11 width=0) (actual time=0.007..0.007 rows=8.00 loops=1)
```

```
Index Cond: (i2 = 898732)
Index Searches: 1
Buffers: shared hit=3
Planning Time: 0.264 ms
Execution Time: 0.047 ms
(15 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 88.5 MB, so the total space needed is 531 MB, over three times the space used by the bloom index.

### F.6.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

### F.6.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

### F.6.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

## F.7. btree\_gin — GIN operator classes with B-tree behavior

`btree_gin` provides GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.7.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

### F.7.2. Authors

Teodor Sigaev (<[teodor@stack.net](mailto:teodor@stack.net)>) and Oleg Bartunov (<[oleg@sai.msu.su](mailto:oleg@sai.msu.su)>). See <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin> for additional information.

## F.8. btree\_gist — GiST operator classes with B-tree behavior

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `bool` and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

By default `btree_gist` builds GiST index with `sortsupport` in *sorted* mode. This usually results in much faster index built speed. It is still possible to revert to buffered built strategy by using the `buffering` parameter when creating the index.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.8.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage INTEGER,
    animal TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
```

```
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint
        "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key
        (cage, animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information.

## F.9. citext — a case-insensitive character string type

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

### Tip

Consider using *nondeterministic collations* (see Section 23.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.9.1. Rationale

The standard approach to doing case-insensitive matches in PostgreSQL has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

### F.9.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry',  
    sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Tom',  
    sha256(random()::text::bytea) );
```

```
INSERT INTO users VALUES ( 'Damian',
    sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'NEAL',
    sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn',
    sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

## F.9.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “`c`” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

## F.9.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing

case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.

- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

## F.9.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

## F.10. cube — a multi-dimensional cube data type

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.10.1. Syntax

Table F.1 shows the valid external representations for the `cube` type.  $x$ ,  $y$ , etc. denote floating-point numbers.

**Table F.1. Cube External Representations**

| External Syntax                      | Meaning                                                                                               |
|--------------------------------------|-------------------------------------------------------------------------------------------------------|
| $x$                                  | A one-dimensional point (or, zero-length one-dimensional interval)                                    |
| $(x)$                                | Same as above                                                                                         |
| $x1, x2, \dots, xn$                  | A point in $n$ -dimensional space, represented internally as a zero-volume cube                       |
| $(x1, x2, \dots, xn)$                | Same as above                                                                                         |
| $(x), (y)$                           | A one-dimensional interval starting at $x$ and ending at $y$ or vice versa; the order does not matter |
| $[(x), (y)]$                         | Same as above                                                                                         |
| $(x1, \dots, xn), (y1, \dots, yn)$   | An $n$ -dimensional cube represented by a pair of its diagonally opposite corners                     |
| $[(x1, \dots, xn), (y1, \dots, yn)]$ | Same as above                                                                                         |

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so  $[(x), (y)]$  is the same as  $[(x), (y)]$ .

### F.10.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

### F.10.3. Usage

Table F.2 shows the specialized operators provided for type `cube`.

**Table F.2. Cube Operators**

| Operator                          | Description                                     |
|-----------------------------------|-------------------------------------------------|
| <code>cube &amp;&amp; cube</code> | <code>→ boolean</code><br>Do the cubes overlap? |
| <code>cube @&gt; cube</code>      | <code>→ boolean</code>                          |

| Operator                         | Description                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  | Does the first cube contain the second?                                                                                                                                                                                                                                                                                                           |
| <code>cube &lt;@ cube</code>     | <code>→ boolean</code><br>Is the first cube contained in the second?                                                                                                                                                                                                                                                                              |
| <code>cube -&gt; integer</code>  | <code>→ float8</code><br>Extracts the $n$ -th coordinate of the cube (counting from 1).                                                                                                                                                                                                                                                           |
| <code>cube ~&gt; integer</code>  | <code>→ float8</code><br>Extracts the $n$ -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of $k$ -th dimension, $n = 2 * k$ means upper bound of $k$ -th dimension. Negative $n$ denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support. |
| <code>cube &lt;-&gt; cube</code> | <code>→ float8</code><br>Computes the Euclidean distance between the two cubes.                                                                                                                                                                                                                                                                   |
| <code>cube &lt;#&gt; cube</code> | <code>→ float8</code><br>Computes the taxicab (L-1 metric) distance between the two cubes.                                                                                                                                                                                                                                                        |
| <code>cube &lt;=&gt; cube</code> | <code>→ float8</code><br>Computes the Chebyshev (L-inf metric) distance between the two cubes.                                                                                                                                                                                                                                                    |

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.3 shows the available functions.

**Table F.3. Cube Functions**

| Function                   | Description<br>Example(s)                                                           |
|----------------------------|-------------------------------------------------------------------------------------|
| <code>cube (float8)</code> | <code>→ cube</code><br>Makes a one dimensional cube with both coordinates the same. |

| Function                                           | Description                                                                                                                                                                                                | Example(s)                                                                  |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
|                                                    |                                                                                                                                                                                                            | <code>cube(1) → (1)</code>                                                  |
| <code>cube(float8, float8) → cube</code>           | Makes a one dimensional cube.                                                                                                                                                                              | <code>cube(1, 2) → (1), (2)</code>                                          |
| <code>cube(float8[]) → cube</code>                 | Makes a zero-volume cube using the coordinates defined by the array.                                                                                                                                       | <code>cube(ARRAY[1, 2, 3]) → (1, 2, 3)</code>                               |
| <code>cube(float8[], float8[]) → cube</code>       | Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.                                                                                   | <code>cube(ARRAY[1, 2], ARRAY[3, 4]) → (1, 2), (3, 4)</code>                |
| <code>cube(cube, float8) → cube</code>             | Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.     | <code>cube('(1, 2), (3, 4)')::cube, 5) → (1, 2, 5), (3, 4, 5)</code>        |
| <code>cube(cube, float8, float8) → cube</code>     | Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.                                                                    | <code>cube('(1, 2), (3, 4)')::cube, 5, 6) → (1, 2, 5), (3, 4, 6)</code>     |
| <code>cube_dim(cube) → integer</code>              | Returns the number of dimensions of the cube.                                                                                                                                                              | <code>cube_dim('(1, 2), (3, 4)') → 2</code>                                 |
| <code>cube_ll_coord(cube, integer) → float8</code> | Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.                                                                                                                           | <code>cube_ll_coord('(1, 2), (3, 4)', 2) → 2</code>                         |
| <code>cube_ur_coord(cube, integer) → float8</code> | Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.                                                                                                                          | <code>cube_ur_coord('(1, 2), (3, 4)', 2) → 4</code>                         |
| <code>cube_is_point(cube) → boolean</code>         | Returns true if the cube is a point, that is, the two defining corners are the same.                                                                                                                       | <code>cube_is_point(cube(1, 1)) → t</code>                                  |
| <code>cube_distance(cube, cube) → float8</code>    | Returns the distance between two cubes. If both cubes are points, this is the normal distance function.                                                                                                    | <code>cube_distance('(1, 2)', '(3, 4)') → 2.8284271247461903</code>         |
| <code>cube_subset(cube, integer[]) → cube</code>   | Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired. | <code>cube_subset(cube('(1, 3, 5), (6, 7, 8)'), ARRAY[2]) → (3), (7)</code> |

| Function                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Example(s)                                                                                        |

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <code>cube_subset(cube(' (1,3,5)', (6,7,8)'), ARRAY[3,2,1,1]) → (5, 3, 1, 1), (8, 7, 6, 6)</code> |
| <code>cube_union ( cube, cube ) → cube</code>                    | Produces the union of two cubes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <code>cube_union(' (1,2)', ' (3,4)' ) → (1, 2), (3, 4)</code>                                     |
| <code>cube_inter ( cube, cube ) → cube</code>                    | Produces the intersection of two cubes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <code>cube_inter(' (1,2)', ' (3,4)' ) → (3, 4), (1, 2)</code>                                     |
| <code>cube_enlarge ( c cube, r double, n integer ) → cube</code> | Increases the size of the cube by the specified radius <i>r</i> in at least <i>n</i> dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius <i>r</i> . Lower-left coordinates are decreased by <i>r</i> and upper-right coordinates are increased by <i>r</i> . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when <i>r</i> < 0) then both coordinates are set to their average. If <i>n</i> is greater than the number of defined dimensions and the cube is being enlarged ( <i>r</i> > 0), then extra dimensions are added to make <i>n</i> altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points. | <code>cube_enlarge(' (1,2), (3,4)', 0.5, 3) → (0.5, 1.5, -0.5), (3.5, 4.5, 0.5)</code>            |

## F.10.4. Defaults

This union:

```
select cube_union(' (0,5,2), (2,3,1)', '0');
cube_union
-----
(0, 0, 0), (2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection:

```
select cube_inter(' (0,-1), (1,1)', ' (-2), (2)' );
cube_inter
-----
(0, 0), (1, 0)
(1 row)
```

In all binary operations on differently-dimensional cubes, the lower-dimensional one is assumed to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union(' (0,5,2), (2,3,1)', ' (0,0,0), (0,0,0)' );
cube_inter(' (0, -1), (1,1)', ' (-2,0), (2,0)' );
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

## F.10.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

## F.10.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

## F.11. dblink — connect to other PostgreSQL databases

`dblink` is a module that supports connections to other PostgreSQL databases from within a database session.

`dblink` can report the following wait events under the wait event type `Extension`.

`DblinkConnect`

Waiting to establish a connection to a remote server.

`DblinkGetConnect`

Waiting to establish a connection to a remote server when it could not be found in the list of already-opened connections.

`DblinkGetResult`

Waiting to receive the results of a query from a remote server.

See also `postgres_fdw`, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

## dblink\_connect

`dblink_connect` — opens a persistent connection to a remote database

## Synopsis

```
dblink_connect(text connstr) returns text  
dblink_connect(text connname, text connstr) returns text
```

## Description

`dblink_connect()` establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as `CREATE SERVER` and `CREATE USER MAPPING`.

## Arguments

*connname*

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

*connstr*

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=.` For details see Section 32.1.1. Alternatively, the name of a foreign server.

## Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

## Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

The foreign-data wrapper `dblink_fdw` has an additional Boolean option `use_scram_passthrough` that controls whether `dblink` will use the SCRAM pass-through authentication to connect to the remote database. With SCRAM pass-through authentication, `dblink` uses SCRAM-hashed secrets instead of plain-text user passwords to connect to the remote server. This avoids storing plain-text user passwords in PostgreSQL system catalogs. See the documentation of the equivalent `use_scram_passthrough` option of `postgres_fdw` for further details and restrictions.

Only superusers may use `dblink_connect` to create connections that use neither password authentication, SCRAM pass-through, nor GSSAPI-authentication. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-
csearch_path=');
dblink_connect
-----
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connections that don't use SCRAM pass-through
--       require password
--       authentication for this to work properly. Otherwise, you
--       will receive
--       the following error from dblink_connect():
--       ERROR: password is required
--       DETAIL: Non-superuser cannot connect if the server does
--       not request a password.
--       HINT: Target server's authentication method must be
--       changed.

```

## **dblink\_connect\_u**

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

## **Synopsis**

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

## **Description**

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

## dblink\_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

### Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

### Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

### Arguments

*connname*

The name of a named connection to be closed.

### Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

### Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
OK
(1 row)
```

## dblink

`dblink` — executes a query in a remote database

## Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns
  setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof
  record
dblink(text sql [, bool fail_on_error]) returns setof record
```

## Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

## Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the **FROM** clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what **\*** should expand to, and what **prname** in the **WHERE** clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the **FROM** clause. The column names need not match, however, and **dblink** does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the **FROM** clause.

## Notes

A convenient way to use **dblink** with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select prname, prosrc from pg_proc')
    AS t1(prname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE prname LIKE 'bytea%';
```

## Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select prname, prosrc from pg_proc')
  AS t1(prname name, prosrc text) WHERE prname LIKE 'bytea%';
 prname  | prosrc
```

```
-----+-----
byteacat | byteacat
byteaeq  | byteaeq
bytealt  | bytealt

(14 rows)
```

## dblink\_exec

`dblink_exec` — executes a command in a remote database

## Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns
text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns
text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

## Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', '{"a0","b0","c0"}')`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either the command's status string or `ERROR`.

## Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
dblink_connect
-----
OK
(1 row)
```

```
SELECT dblink_exec('insert into foo values(21, ''z'',
''{"a0","b0","c0"}''));
dblink_exec
-----
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
dblink_connect
-----
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}''));
dblink_exec
-----
INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values
(''foo''),false);
NOTICE: sql error
DETAIL: ERROR: null value in column "relnamespace" violates not-
null constraint

dblink_exec
-----
ERROR
(1 row)
```

## dblink\_open

`dblink_open` — opens a cursor in a remote database

## Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error])
    returns text
dblink_open(text connname, text cursorname, text sql [, bool
    fail_on_error]) returns text
```

## Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name to assign to this cursor.

*sql*

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either `OK` or `ERROR`.

## Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----  
OK  
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');  
dblink_open
```

```
-----  
OK  
(1 row)
```

## dblink\_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

## Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error])
  returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool
  fail_on_error]) returns setof record
```

## Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to fetch from.

*howmany*

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

## Notes

On a mismatch between the number of return columns specified in the FROM clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote FETCH has been done.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
```

OK  
(1 row)

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc
where proname like ''bytea%'');
dblink_open
```

OK  
(1 row)

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
```

| funcname | source   |
|----------|----------|
| byteacat | byteacat |
| byteacmp | byteacmp |
| byteaeq  | byteaeq  |
| byteage  | byteage  |
| byteagt  | byteagt  |

(5 rows)

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
```

| funcname  | source    |
|-----------|-----------|
| byteain   | byteain   |
| byteale   | byteale   |
| bytealike | bytealike |
| bytealt   | bytealt   |
| byteane   | byteane   |

(5 rows)

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
```

| funcname   | source     |
|------------|------------|
| byteanlike | byteanlike |
| byteaout   | byteaout   |

(2 rows)

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
```

| funcname | source |
|----------|--------|
|----------|--------|

(0 rows)

## dblink\_close

`dblink_close` — closes a cursor in a remote database

## Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error])
returns text
```

## Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to close.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either `OK` or `ERROR`.

## Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
```

```
dblink_close
-----
OK
(1 row)
```

## **dblink\_get\_connections**

`dblink_get_connections` — returns the names of all open named dblink connections

### **Synopsis**

`dblink_get_connections()` returns `text[]`

### **Description**

`dblink_get_connections` returns an array of the names of all open named dblink connections.

### **Return Value**

Returns a text array of connection names, or NULL if none.

### **Examples**

```
SELECT dblink_get_connections();
```

## **dblink\_error\_message**

`dblink_error_message` — gets last error message on the named connection

### **Synopsis**

`dblink_error_message(text connname)` returns text

### **Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns last error message, or OK if there has been no error in this connection.

### **Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

### **Examples**

```
SELECT dblink_error_message('dtest1');
```

## dblink\_send\_query

`dblink_send_query` — sends an async query to a remote database

## Synopsis

`dblink_send_query(text connname, text sql)` returns `int`

## Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

## Arguments

*connname*

Name of the connection to use.

*sql*

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

## Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

## Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 <
3');
```

## dblink\_is\_busy

`dblink_is_busy` — checks if connection is busy with an async query

## Synopsis

```
dblink_is_busy(text connname) returns int
```

## Description

`dblink_is_busy` tests whether an async query is in progress.

## Arguments

*connname*

Name of the connection to check.

## Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

## Examples

```
SELECT dblink_is_busy('dtest1');
```

## dblink\_get\_notify

dblink\_get\_notify — retrieve async notifications on a connection

## Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int,  
    extra text)  
dblink_get_notify(text connname) returns setof (notify_name text,  
    be_pid int, extra text)
```

## Description

dblink\_get\_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink\_exec. For details see LISTEN and NOTIFY.

## Arguments

*connname*

The name of a named connection to get notifications on.

## Return Value

Returns setof (notify\_name text, be\_pid int, extra text), or an empty set if none.

## Examples

```
SELECT dblink_exec('LISTEN virtual');  
dblink_exec  
-----  
LISTEN  
(1 row)  
  
SELECT * FROM dblink_get_notify();  
notify_name | be_pid | extra  
-----+-----+-----  
(0 rows)  
  
NOTIFY virtual;  
NOTIFY  
  
SELECT * FROM dblink_get_notify();  
notify_name | be_pid | extra  
-----+-----+-----  
virtual    | 1229 |  
(1 row)
```

## dblink\_get\_result

`dblink_get_result` — gets an async query result

## Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns  
setof record
```

## Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

## Arguments

*connname*

Name of the connection to use.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

## Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink( )`, which avoids memory bloat by spooling large result sets to disk.

## Examples

```
contrib_regression=# SELECT dblink_connect('dtest1',  
    'dbname=contrib_regression');  
dblink_connect  
-----
```

OK  
(1 row)

```
contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo
where f1 < 3') AS t1;
t1
```

```
-----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
```

```
-----+-----+-----
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
```

```
-----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo
where f1 < 3; select * from foo where f1 > 6') AS t1;
t1
```

```
-----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
```

```
-----+-----+-----
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
```

```
-----+-----+-----
7 | h | {a7,b7,c7}
8 | i | {a8,b8,c8}
9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(4 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
```

```
-----+-----+-----
(0 rows)
```

## **dblink\_cancel\_query**

`dblink_cancel_query` — cancels any active query on the named connection

### **Synopsis**

`dblink_cancel_query(text connname)` returns `text`

### **Description**

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns OK if the cancel request has been sent, or the text of an error message on failure.

### **Examples**

```
SELECT dblink_cancel_query('dtest1');
```

## dblink\_get\_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

## Synopsis

`dblink_get_pkey(text relname)` returns `setof dblink_pkey_results`

## Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

## Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

## Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

## Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
         1 | f1  
         2 | f2  
         3 | f3  
(3 rows)
```

## dblink\_build\_sql\_insert

`dblink_build_sql_insert` — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous

versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

## Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}',
    '{"1", "b''a"}');
          dblink_build_sql_insert
-----
INSERT INTO foo(f1,f2,f3) VALUES('1','b''a','1')
(1 row)
```

## dblink\_build\_sql\_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

### Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL DELETE command that will delete the row with the given primary key values.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');
```

`dblink_build_sql_delete`

```
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

## dblink\_build\_sql\_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous

versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

## Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}',
                                '{"1", "b"}');
                                dblink_build_sql_update
-----
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

## F.12. dict\_int — example full-text search dictionary for integers

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.12.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

### F.12.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG
= true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
ts_lexize
-----
{123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR int, uint WITH intdict;
```

## F.13. dict\_xsyn — example synonym full-text search dictionary

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

### F.13.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the PostgreSQL installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

```
word syn1 syn2 syn3
```

- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$$SHAREDIR/tsearch_data/`, for an example.

### F.13.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
      KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
      ts_lexize
```

```
-----  
{syn1, syn2, syn3}  
  
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',  
      KEEPORIG=true);  
ALTER TEXT SEARCH DICTIONARY  
  
mydb=# SELECT ts_lexize('xsyn', 'word');  
          ts_lexize  
-----  
{word, syn1, syn2, syn3}  
  
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',  
      KEEPORIG=false, MATCHSYNONYMS=true);  
ALTER TEXT SEARCH DICTIONARY  
  
mydb=# SELECT ts_lexize('xsyn', 'syn1');  
          ts_lexize  
-----  
{syn1, syn2, syn3}  
  
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',  
      KEEPORIG=true, MATCHORIG=false, KEPSYNONYMS=false);  
ALTER TEXT SEARCH DICTIONARY  
  
mydb=# SELECT ts_lexize('xsyn', 'syn1');  
          ts_lexize  
-----  
{word}
```

Real-world usage will involve including it in a text search configuration as described in Chapter 12.  
That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english  
      ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

## F.14. earthdistance — calculate great-circle distances

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the PostGIS<sup>1</sup> project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

### Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

### F.14.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A *domain* `earth` over type `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F.4.

**Table F.4. Cube-Based Earthdistance Functions**

| Function                                | Description                                                                                                                                   |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>earth() → float8</code>           | Returns the assumed radius of the Earth.                                                                                                      |
| <code>sec_to_gc(float8) → float8</code> | Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them. |

<sup>1</sup> <https://postgis.net/>

| Function                                              | Description                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gc_to_sec ( float8 ) → float8</code>            | Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.                                                                                                                                                                                               |
| <code>ll_to_earth ( float8, float8 ) → earth</code>   | Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.                                                                                                                                                                                                          |
| <code>latitude ( earth ) → float8</code>              | Returns the latitude in degrees of a point on the surface of the Earth.                                                                                                                                                                                                                                                                     |
| <code>longitude ( earth ) → float8</code>             | Returns the longitude in degrees of a point on the surface of the Earth.                                                                                                                                                                                                                                                                    |
| <code>earth_distance ( earth, earth ) → float8</code> | Returns the great circle distance between two points on the surface of the Earth.                                                                                                                                                                                                                                                           |
| <code>earth_box ( earth, float8 ) → cube</code>       | Returns a box suitable for an indexed search using the <code>cube @&gt;</code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query. |

## F.14.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F.5.

**Table F.5. Point-Based Earthdistance Operators**

| Operator                                    | Description                                                                       |
|---------------------------------------------|-----------------------------------------------------------------------------------|
| <code>point &lt;@&gt; point → float8</code> | Computes the distance in statute miles between two points on the Earth's surface. |

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

## F.15. file\_fdw — access data files in the server's file system

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see `COPY` for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

**filename**

Specifies the file to be read. Relative paths are relative to the data directory. Either **filename** or **program** must be specified, but not both.

**program**

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either **program** or **filename** must be specified, but not both.

**format**

Specifies the data format, the same as `COPY`'s `FORMAT` option.

**header**

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

**delimiter**

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

**quote**

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

**escape**

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

**null**

Specifies the data null string, the same as `COPY`'s `NULL` option.

**default**

Specifies the string that represents a default value, the same as `COPY`'s `DEFAULT` option.

**encoding**

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

**on\_error**

Specifies how to behave when encountering an error converting a column's input value into its data type, the same as `COPY`'s `ON_ERROR` option.

**reject\_limit**

Specifies the maximum number of errors tolerated while converting a column's input value to its data type, the same as `COPY`'s `REJECT_LIMIT` option.

## `log_verbosity`

Specifies the amount of messages emitted by `file_fdw`, the same as `COPY`'s `LOG_VERBOSITY` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

## `force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.

## `force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in `COPY`'s `FORCE_NULL` option.

`COPY`'s `FORCE_QUOTE` option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role `pg_read_server_files` (to use a filename) or the role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

## Example F.1. Create a Foreign Table for PostgreSQL CSV Logs

One of the obvious uses for `file_fdw` is to make the PostgreSQL activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,  
    hint text,  
    internal_query text,  
    internal_query_pos integer,  
    context text,  
    query text,  
    query_pos integer,  
    location text,  
    application_name text,  
    backend_type text,  
    leader_pid integer,  
    query_id bigint  
) SERVER pglog  
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

### **Example F.2. Create a Foreign Table with an Option on a Column**

To set the `force_null` option for a column, use the `OPTIONS` keyword.

```
CREATE FOREIGN TABLE films (  
    code char(5) NOT NULL,  
    title text NOT NULL,  
    rating text OPTIONS (force_null 'true')  
) SERVER film_server  
OPTIONS ( filename 'films/db.csv', format 'csv' );
```

## F.16. fuzzystmatch — determine string similarities and distance

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

### Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8). Use `daitch_mokotoff` or `levenshtein` with such data.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.16.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text  
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');  
  
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');  
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne',  
  'Andrew');  
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne',  
  'Margaret');  
  
CREATE TABLE s (nm text);  
  
INSERT INTO s VALUES ('john');  
INSERT INTO s VALUES ('joan');  
INSERT INTO s VALUES ('wobbly');  
INSERT INTO s VALUES ('jack');  
  
SELECT * FROM s WHERE soundex(nm) = soundex('john');  
  
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

## F.16.2. Daitch-Mokotoff Soundex

Like the original Soundex system, Daitch-Mokotoff Soundex matches similar-sounding names by converting them to the same code. However, Daitch-Mokotoff Soundex is significantly more useful for non-English names than the original system. Major improvements over the original system include:

- The code is based on the first six meaningful letters rather than four.
- A letter or combination of letters maps into ten possible codes rather than seven.
- Where two consecutive letters have a single sound, they are coded as a single number.
- When a letter or combination of letters may have different sounds, multiple codes are emitted to cover all possibilities.

This function generates the Daitch-Mokotoff soundex codes for its input:

`daitch_mokotoff(source text)` returns `text[]`

The result may contain one or more codes depending on how many plausible pronunciations there are, so it is represented as an array.

Since a Daitch-Mokotoff soundex code consists of only 6 digits, *source* should be preferably a single word or name.

Here are some examples:

```
SELECT daitch_mokotoff('George');
       daitch_mokotoff
-----
      {595000}

SELECT daitch_mokotoff('John');
       daitch_mokotoff
-----
      {160000,460000}

SELECT daitch_mokotoff('Bierschbach');
               daitch_mokotoff
-----
      {794575,794574,794750,794740,745750,745740,747500,747400}

SELECT daitch_mokotoff('Schwartzenegger');
       daitch_mokotoff
-----
      {479465}
```

For matching of single names, returned text arrays can be matched directly using the `&&` operator: any overlap can be considered a match. A GIN index may be used for efficiency, see Section 65.4 and this example:

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_dm ON s USING gin (daitch_mokotoff(nm)) WITH
(fastupdate = off);

INSERT INTO s (nm) VALUES
  ('Schwartzenegger'),
  ('John'),
  ('James'),
```

```
    ('Steinman'),
    ('Steinmetz');

SELECT * FROM s WHERE daitch_mokotoff(nm) &&
    daitch_mokotoff('Swartzenegger');
SELECT * FROM s WHERE daitch_mokotoff(nm) &&
    daitch_mokotoff('Jane');
SELECT * FROM s WHERE daitch_mokotoff(nm) &&
    daitch_mokotoff('Jens');
```

For indexing and matching of any number of names in any order, Full Text Search features can be used. See Chapter 12 and this example:

```
CREATE FUNCTION soundex_tsvector(v_name text) RETURNS tsvector
BEGIN ATOMIC
    SELECT to_tsvector('simple',
        string_agg(array_to_string(daitch_mokotoff(n),
            ' '), ' '))
    FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE FUNCTION soundex_tsquery(v_name text) RETURNS tsquery
BEGIN ATOMIC
    SELECT string_agg('(' || array_to_string(daitch_mokotoff(n), '|')
        || ')', '&')::tsquery
    FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE TABLE s (nm text);
CREATE INDEX ix_s_txt ON s USING gin (soundex_tsvector(nm)) WITH
    (fastupdate = off);

INSERT INTO s (nm) VALUES
    ('John Doe'),
    ('Jane Roe'),
    ('Public John Q.'),
    ('George Best'),
    ('John Yamson');

SELECT * FROM s WHERE soundex_tsvector(nm) @@
    soundex_tsquery('john');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('jane
    doe');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john
    public');
SELECT * FROM s WHERE soundex_tsvector(nm) @@
    soundex_tsquery('besst, giorgio');
SELECT * FROM s WHERE soundex_tsvector(nm) @@
    soundex_tsquery('Jameson John');
```

If it is desired to avoid recalculation of soundex codes during index rechecks, an index on a separate column can be used instead of an index on an expression. A stored generated column can be used for this; see Section 5.4.

## F.16.3. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(source text, target text, ins_cost int, del_cost int,
  sub_cost int) returns int
levenshtein(source text, target text) returns int
levenshtein_less_equal(source text, target text, ins_cost int,
  del_cost int, sub_cost int, max_d int) returns int
levenshtein_less_equal(source text, target text, max_d int) returns
  int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
                2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
 levenshtein
-----
                3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
-----
                        3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
-----
                        4
(1 row)
```

## F.16.4. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(source text, max_output_length int) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
KM
(1 row)
```

## F.16.5. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(source text) returns text
dmetaphone_alt(source text) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
-----
KMP
(1 row)
```

## F.17. hstore — hstore key/value datatype

This module implements the `hstore` data type for storing sets of key/value pairs within a single PostgreSQL value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.17.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more *key => value* pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
"a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “`NULL`”.

#### Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

### F.17.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in Table F.6, the functions in Table F.7.

**Table F.6. hstore Operators**

| Operator                                       | Description                                                                                            | Example(s)                                                                                                    |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>hstore -&gt; text → text</code>          | Returns value associated with given key, or NULL if not present.                                       | <code>'a=&gt;x, b=&gt;y'::hstore -&gt; 'a' → x</code>                                                         |
| <code>hstore -&gt; text[] → text[]</code>      | Returns values associated with given keys, or NULL if not present.                                     | <code>'a=&gt;x, b=&gt;y, c=&gt;z'::hstore -&gt; ARRAY['c', 'a'] → {"z", "x"}</code>                           |
| <code>hstore    hstore → hstore</code>         | Concatenates two hstores.                                                                              | <code>'a=&gt;b, c=&gt;d'::hstore    'c=&gt;x, d=&gt;q'::hstore → "a"=&gt;"b", "c"=&gt;"x", "d"=&gt;"q"</code> |
| <code>hstore ? text → boolean</code>           | Does hstore contain key?                                                                               | <code>'a=&gt;1'::hstore ? 'a' → t</code>                                                                      |
| <code>hstore ?&amp; text[] → boolean</code>    | Does hstore contain all the specified keys?                                                            | <code>'a=&gt;1, b=&gt;2'::hstore ?&amp; ARRAY['a', 'b'] → t</code>                                            |
| <code>hstore ?  text[] → boolean</code>        | Does hstore contain any of the specified keys?                                                         | <code>'a=&gt;1, b=&gt;2'::hstore ?  ARRAY['b', 'c'] → t</code>                                                |
| <code>hstore @&gt; hstore → boolean</code>     | Does left operand contain right?                                                                       | <code>'a=&gt;b, b=&gt;1, c=&gt;NULL'::hstore @&gt; 'b=&gt;1' → t</code>                                       |
| <code>hstore &lt;@ hstore → boolean</code>     | Is left operand contained in right?                                                                    | <code>'a=&gt;c'::hstore &lt;@ 'a=&gt;b, b=&gt;1, c=&gt;NULL' → f</code>                                       |
| <code>hstore - text → hstore</code>            | Deletes key from left operand.                                                                         | <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'b'::text → "a"=&gt;"1", "c"=&gt;"3"</code>                       |
| <code>hstore - text[] → hstore</code>          | Deletes keys from left operand.                                                                        | <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - ARRAY['a', 'b'] → "c"=&gt;"3"</code>                              |
| <code>hstore - hstore → hstore</code>          | Deletes pairs from left operand that match pairs in the right operand.                                 | <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'a=&gt;4, b=&gt;2'::hstore → "a"=&gt;"1", "c"=&gt;"3"</code>      |
| <code>anyelement #= hstore → anyelement</code> | Replaces fields in the left operand (which must be a composite type) with matching values from hstore. | <code>ROW(1,3) #= 'f1=&gt;11'::hstore → (11,3)</code>                                                         |
| <code>%% hstore → text[]</code>                |                                                                                                        |                                                                                                               |

| <b>Operator</b> | <b>Description</b><br><b>Example(s)</b>                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | Converts <code>hstore</code> to an array of alternating keys and values.<br><code>%% 'a=&gt;foo, b=&gt;bar': :hstore → {a, foo, b, bar}</code>                                  |
|                 | <code>## hstore → text[]</code><br>Converts <code>hstore</code> to a two-dimensional key/value array.<br><code>## 'a=&gt;foo, b=&gt;bar': :hstore → {{a, foo}, {b, bar}}</code> |

**Table F.7. `hstore` Functions**

| <b>Function</b>                                                                                                                                                                                                                                                                                                              | <b>Description</b><br><b>Example(s)</b> |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|

|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>hstore_to_array(hstore) → text[]</code>                   | Extracts an <code>hstore</code> 's keys and values as an array of alternating keys and values.                                                                                                                    | <code>hstore_to_array('a=&gt;1,b=&gt;2') → {a,1,b,2}</code>                                                                                                                                                                 |
| <code>hstore_to_matrix(hstore) → text[]</code>                  | Extracts an <code>hstore</code> 's keys and values as a two-dimensional array.                                                                                                                                    | <code>hstore_to_matrix('a=&gt;1,b=&gt;2') → {{a,1},{b,2}}</code>                                                                                                                                                            |
| <code>hstore_to_json(hstore) → json</code>                      | Converts an <code>hstore</code> to a <code>json</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>json</code> .   | <code>hstore_to_json('a key'=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>  |
| <code>hstore_to_jsonb(hstore) → jsonb</code>                    | Converts an <code>hstore</code> to a <code>jsonb</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>jsonb</code> . | <code>hstore_to_jsonb('a key'=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code> |
| <code>hstore_to_json_loose(hstore) → json</code>                | Converts an <code>hstore</code> to a <code>json</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.                                                          | <code>hstore_to_json_loose('a key'=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</code>   |
| <code>hstore_to_jsonb_loose(hstore) → jsonb</code>              | Converts an <code>hstore</code> to a <code>jsonb</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.                                                         | <code>hstore_to_jsonb_loose('a key'=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</code>  |
| <code>slice(hstore, text[]) → hstore</code>                     | Extracts a subset of an <code>hstore</code> containing only the specified keys.                                                                                                                                   | <code>slice('a=&gt;1,b=&gt;2,c=&gt;3'::hstore, ARRAY['b','c','x']) → "b"=&gt;"2", "c"=&gt;"3"</code>                                                                                                                        |
| <code>each(hstore) → setof record (key text, value text)</code> | Extracts an <code>hstore</code> 's keys and values as a set of records.                                                                                                                                           | <code>select * from each('a=&gt;1,b=&gt;2') →</code><br><br><div> <div>key   value</div> <div>-----+-----</div> <div>a   1</div> </div>                                                                                     |

| Function                                                      | Description                                                                                                          | Example(s)                                                                        |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
|                                                               |                                                                                                                      | <code>b   2</code>                                                                |
| <code>exist(hstore, text) → boolean</code>                    | Does <code>hstore</code> contain key?                                                                                | <code>exist('a=&gt;1', 'a') → t</code>                                            |
| <code>defined(hstore, text) → boolean</code>                  | Does <code>hstore</code> contain a non-NULL value for key?                                                           | <code>defined('a=&gt;NULL', 'a') → f</code>                                       |
| <code>delete(hstore, text) → hstore</code>                    | Deletes pair with matching key.                                                                                      | <code>delete('a=&gt;1, b=&gt;2', 'b') → "a"=&gt;"1"</code>                        |
| <code>delete(hstore, text[]) → hstore</code>                  | Deletes pairs with matching keys.                                                                                    | <code>delete('a=&gt;1, b=&gt;2, c=&gt;3', ARRAY['a', 'b']) → "c"=&gt;"3"</code>   |
| <code>delete(hstore, hstore) → hstore</code>                  | Deletes pairs matching those in the second argument.                                                                 | <code>delete('a=&gt;1, b=&gt;2', 'a=&gt;4, b=&gt;2'::hstore) → "a"=&gt;"1"</code> |
| <code>populate_record(anyelement, hstore) → anyelement</code> | Replaces fields in the left operand (which must be a composite type) with matching values from <code>hstore</code> . | <code>populate_record(ROW(1,2), 'f1=&gt;42'::hstore) → (42,2)</code>              |

In addition to these operators and functions, values of the `hstore` type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type `text` can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;
 h
---
 b
(1 row)

UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
 h
-----
 "a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns `NULL` if the subscript is `NULL` or that key does not exist in the `hstore`. (Thus, a subscripted fetch is not greatly different from the `->` operator.) A subscripted update fails if the subscript is `NULL`; otherwise, it replaces the value for that key, adding an entry to the `hstore` if the key does not already exist.

## F.17.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h  
gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```
CREATE INDEX hidx ON testhstore USING HASH (h);
```

## F.17.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h['c'] = '3';
```

Another way to do the same thing is:

```
UPDATE tab SET h = h || hstore('c', '3');
```

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

```
UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);  
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;  
      hstore
```

```
-----  
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
```

(1 row)

Convert an hstore to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                              '"col1"=>"456", "col2"=>"zzz"');
 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

## F.17.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM
testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
 key    | count
-----+-----
line    |    883
query   |    207
pos     |    203
node    |    202
space   |    197
status  |    195
public  |    194
```

|       |  |     |
|-------|--|-----|
| title |  | 190 |
| org   |  | 189 |
| ..... |  |     |

## F.17.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol  
|| '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

## F.17.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extension for PL/Python is called `hstore_plpython3u`. If you use it, `hstore` values are mapped to Python dictionaries.

## F.17.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

## F.18. intagg — integer aggregator and enumerator

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

### F.18.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

### F.18.2. Sample Uses

Many database systems have the notion of a many to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left_table (id INT PRIMARY KEY, ...);
CREATE TABLE right_table (id INT PRIMARY KEY, ...);
CREATE TABLE many_to_many(id_left INT REFERENCES left_table,
                           id_right INT REFERENCES right_table);
```

It is typically used like this:

```
SELECT right_table.*
FROM right_table JOIN many_to_many ON (right_table.id =
    many_to_many.id_right)
WHERE many_to_many.id_left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `many_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT id_left, int_array_aggregate(id_right) AS rights
  FROM many_to_many
  GROUP BY id_left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT id_left, int_array_enum(rights) FROM summary WHERE id_left
= item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT id_left, id_right FROM many_to_many WHERE id_left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `many_to_many` must index scan and fetch a row for each entry.

On one system, an EXPLAIN showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `many_to_many` table, which was replaced by:

```
SELECT id_right, count(id_right) FROM
  ( SELECT id_left, int_array_enum(rights) AS id_right
    FROM summary
    JOIN (SELECT id FROM left_table
          WHERE id = item) AS lefts
    ON (summary.id_left = lefts.id)
  ) AS list
GROUP BY id_right
ORDER BY count DESC;
```

## F.19. intarray — manipulate arrays of integers

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.19.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in Table F.8, the operators in Table F.9.

**Table F.8. intarray Functions**

| Function                                                                                       | Description                                                                                                         | Example(s)                                                                                                                   |
|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>icount ( integer[] ) → integer</code>                                                    | Returns the number of elements in the array.                                                                        | <code>icount( '{1,2,3}'::integer[] ) → 3</code>                                                                              |
| <code>sort ( integer[], dir text ) → integer[]</code>                                          | Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> . | <code>sort( '{1,3,2}'::integer[], 'desc' ) → {3,2,1}</code>                                                                  |
| <code>sort ( integer[] ) → integer[]</code><br><code>sort_asc ( integer[] ) → integer[]</code> | Sorts in ascending order.                                                                                           | <code>sort(array[11,77,44]) → {11,44,77}</code>                                                                              |
| <code>sort_desc ( integer[] ) → integer[]</code>                                               | Sorts in descending order.                                                                                          | <code>sort_desc(array[11,77,44]) → {77,44,11}</code>                                                                         |
| <code>uniq ( integer[] ) → integer[]</code>                                                    | Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates.                            | <code>uniq( '{1,2,2,3,1,1}'::integer[] ) → {1,2,3,1}</code><br><code>uniq(sort( '{1,2,3,2,1}'::integer[] )) → {1,2,3}</code> |
| <code>idx ( integer[], item integer ) → integer</code>                                         | Returns index of the first array element matching <i>item</i> , or 0 if no match.                                   | <code>idx(array[11,22,33,22,11], 22) → 2</code>                                                                              |
| <code>subarray ( integer[], start integer, len integer ) → integer[]</code>                    | Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements.                     | <code>subarray( '{1,2,3,2,1}'::integer[], 2, 3 ) → {2,3,2}</code>                                                            |
| <code>subarray ( integer[], start integer ) → integer[]</code>                                 | Extracts the portion of the array starting at position <i>start</i> .                                               | <code>subarray( '{1,2,3,2,1}'::integer[], 2 ) → {2,3,2,1}</code>                                                             |

| Function                                                                                                       |
|----------------------------------------------------------------------------------------------------------------|
| <b>Description</b><br><b>Example(s)</b>                                                                        |
| <code>intset ( integer ) → integer[]</code><br>Makes a single-element array.<br><code>intset(42) → {42}</code> |

**Table F.9. intarray Operators**

| Operator                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b>                                                                                                                                                            |
| <code>integer[] &amp;&amp; integer[] → boolean</code><br>Do arrays overlap (have at least one element in common)?                                                             |
| <code>integer[] @&gt; integer[] → boolean</code><br>Does left array contain right array?                                                                                      |
| <code>integer[] &lt;@ integer[] → boolean</code><br>Is left array contained in right array?                                                                                   |
| <code># integer[] → integer</code><br>Returns the number of elements in the array.                                                                                            |
| <code>integer[] # integer → integer</code><br>Returns index of the first array element matching the right argument, or 0 if no match.<br>(Same as <code>idx</code> function.) |
| <code>integer[] + integer → integer[]</code><br>Adds element to end of array.                                                                                                 |
| <code>integer[] + integer[] → integer[]</code><br>Concatenates the arrays.                                                                                                    |
| <code>integer[] - integer → integer[]</code><br>Removes entries matching the right argument from the array.                                                                   |
| <code>integer[] - integer[] → integer[]</code><br>Removes elements of the right array from the left array.                                                                    |
| <code>integer[]   integer → integer[]</code><br>Computes the union of the arguments.                                                                                          |
| <code>integer[]   integer[] → integer[]</code><br>Computes the union of the arguments.                                                                                        |
| <code>integer[] &amp; integer[] → integer[]</code><br>Computes the intersection of the arguments.                                                                             |
| <code>integer[] @@ query_int → boolean</code><br>Does array satisfy query? (see below)                                                                                        |
| <code>query_int ~~ integer[] → boolean</code><br>Does array satisfy query? (commutator of @@)                                                                                 |

The operators `&&`, `@>` and `<@` are equivalent to PostgreSQL's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against

the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query `1&(2|3)` matches arrays that contain 1 and also contain either 2 or 3.

## F.19.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.19.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections
  gist__intbig_ops (siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@
  '1&2'::query_int;
```

## F.19.4. Benchmark

The source directory `contrib/intarray/bench` contains a benchmark test suite, which can be run against an installed PostgreSQL server. (It also requires `DBD:Pg` to be installed.) To run:

```
cd .../contrib/intarray/bench
createdb TEST
```

```
psql -c "CREATE EXTENSION intarray" TEST  
./create_test.pl | psql TEST  
./bench.pl
```

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

## F.19.5. Authors

All work was done by Teodor Sigaev (<[teodor@sigaev.ru](mailto:teodor@sigaev.ru)>) and Oleg Bartunov (<[oleg@sai.msu.su](mailto:oleg@sai.msu.su)>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

## F.20. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.)

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.20.1. Data Types

Table F.10 shows the data types provided by the `isn` module.

**Table F.10. isn Data Types**

| Data Type | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| EAN13     | European Article Numbers, always displayed in the EAN13 display format                |
| ISBN13    | International Standard Book Numbers to be displayed in the new EAN13 display format   |
| ISMN13    | International Standard Music Numbers to be displayed in the new EAN13 display format  |
| ISSN13    | International Standard Serial Numbers to be displayed in the new EAN13 display format |
| ISBN      | International Standard Book Numbers to be displayed in the old short display format   |
| ISMN      | International Standard Music Numbers to be displayed in the old short display format  |
| ISSN      | International Standard Serial Numbers to be displayed in the old short display format |
| UPC       | Universal Product Codes                                                               |

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

## F.20.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

## F.20.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition, there are several specialized functions, shown in Table F.11. In this table, `isn` means any one of the module's data types.

**Table F.11. `isn` Functions**

| Function                                 | Description                                                                                                                                                                                                 |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>make_valid(isn) → isn</code>       | Clears the invalid-check-digit flag of the value.                                                                                                                                                           |
| <code>is_valid(isn) → boolean</code>     | Checks for the presence of the invalid-check-digit flag.                                                                                                                                                    |
| <code>isn_weak(boolean) → boolean</code> | Sets the weak input mode, and returns the new setting. This function is retained for backward compatibility. The recommended way to set weak mode is via the <code>isn.weak</code> configuration parameter. |
| <code>isn_weak() → boolean</code>        |                                                                                                                                                                                                             |

| Function | Description                                                                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | Returns the current status of the weak mode. This function is retained for backward compatibility. The recommended way to check weak mode is via the <code>isbn.weak</code> configuration parameter. |

## F.20.4. Configuration Parameters

`isbn.weak` (boolean)

`isbn.weak` enables the weak input mode, which allows ISBN input values to be accepted even when their check digit is wrong. The default is `false`, which rejects invalid check digits.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example `0-11-000322-5!`. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of marked-as-invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

## F.20.5. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select
  isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
```

```
SELECT ismn('979047213542?');

--Using the weak mode:
SET isn.weak TO true;
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SET isn.weak TO false;

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

## F.20.6. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- [https://en.wikipedia.org/wiki/List\\_of\\_ISBN\\_registration\\_groups](https://en.wikipedia.org/wiki/List_of_ISBN_registration_groups)
- <https://www.isbn-international.org/content/isbn-users-manual/29>
- [https://en.wikipedia.org/wiki/International\\_Standard\\_Music\\_Number](https://en.wikipedia.org/wiki/International_Standard_Music_Number)
- <https://www.ismn-international.org/ranges/tools>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

## F.20.7. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

## F.21. lo — manage large objects

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.21.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a *domain* over the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

### F.21.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

### F.21.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It's a good idea to run vacuumlo occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

## F.21.4. Author

Peter Mount <peter@retep.org.uk>

## F.22. ltree — hierarchical tree-like data type

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.22.1. Definitions

A *label* is a sequence of alphanumeric characters, underscores, and hyphens. Valid alphanumeric character ranges are dependent on the database locale. For example, in C locale, the characters A-Za-z0-9\_ - are allowed. Labels must be no more than 1000 characters long.

Examples: 42, Personal\_Services

A *label path* is a sequence of zero or more labels separated by dots, for example L1.L2.L3, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: Top.Countries.Europe.Russia

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (\*) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

|                      |                                                      |
|----------------------|------------------------------------------------------|
| <code>foo</code>     | <i>Match the exact label path foo</i>                |
| <code>*.foo.*</code> | <i>Match any label path containing the label foo</i> |
| <code>*.foo</code>   | <i>Match any label path whose last label is foo</i>  |

Both star symbols and simple words can be quantified to restrict how many labels they can match:

|                       |                                                                |
|-----------------------|----------------------------------------------------------------|
| <code>*{n}</code>     | <i>Match exactly n labels</i>                                  |
| <code>*{n,}</code>    | <i>Match at least n labels</i>                                 |
| <code>*{n,m}</code>   | <i>Match at least n but not more than m labels</i>             |
| <code>*{,m}</code>    | <i>Match at most m labels – same as *{0,m}</i>                 |
| <code>foo{n,m}</code> | <i>Match at least n but not more than m occurrences of foo</i> |
| <code>foo{,}</code>   | <i>Match any number of occurrences of foo, including zero</i>  |

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, {, }) while the default for a non-star item is to match exactly once (that is, {1}).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <code>@</code> | <i>Match case-insensitively, for example a@ matches A</i>                |
| <code>*</code> | <i>Match any label with this prefix, for example foo* matches foobar</i> |
| <code>%</code> | <i>Match initial underscore-separated words</i>                          |

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.   b.       c.       d.               e.
```

This query will match any label path that:

- a. begins with the label `Top`
  - b. and next has zero to two labels before
  - c. a label beginning with the case-insensitive prefix `sport`
  - d. then has one or more labels, none of which match `football` nor `tennis`
  - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.22.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.12 are available.

**Table F.12. `ltree` Operators**

| Operator                       | Description                                                                 |
|--------------------------------|-----------------------------------------------------------------------------|
| <code>ltree @&gt; ltree</code> | <code>→ boolean</code><br>Is left argument an ancestor of right (or equal)? |

| Operator                                                                                                                                                                    | Description |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| <code>ltree &lt;@ ltree → boolean</code><br>Is left argument a descendant of right (or equal)?                                                                              |             |
| <code>ltree ~ lquery → boolean</code><br><code>lquery ~ ltree → boolean</code><br>Does <code>ltree</code> match <code>lquery</code> ?                                       |             |
| <code>ltree ? lquery[] → boolean</code><br><code>lquery[] ? ltree → boolean</code><br>Does <code>ltree</code> match any <code>lquery</code> in array?                       |             |
| <code>ltree @ ltxtquery → boolean</code><br><code>ltxtquery @ ltree → boolean</code><br>Does <code>ltree</code> match <code>ltxtquery</code> ?                              |             |
| <code>ltree    ltree → ltree</code><br>Concatenates <code>ltree</code> paths.                                                                                               |             |
| <code>ltree    text → ltree</code><br><code>text    ltree → ltree</code><br>Converts text to <code>ltree</code> and concatenates.                                           |             |
| <code>ltree[] @&gt; ltree → boolean</code><br><code>ltree &lt;@ ltree[] → boolean</code><br>Does array contain an ancestor of <code>ltree</code> ?                          |             |
| <code>ltree[] &lt;@ ltree → boolean</code><br><code>ltree @&gt; ltree[] → boolean</code><br>Does array contain a descendant of <code>ltree</code> ?                         |             |
| <code>ltree[] ~ lquery → boolean</code><br><code>lquery ~ ltree[] → boolean</code><br>Does array contain any path matching <code>lquery</code> ?                            |             |
| <code>ltree[] ? lquery[] → boolean</code><br><code>lquery[] ? ltree[] → boolean</code><br>Does <code>ltree</code> array contain any path matching any <code>lquery</code> ? |             |
| <code>ltree[] @ ltxtquery → boolean</code><br><code>ltxtquery @ ltree[] → boolean</code><br>Does array contain any path matching <code>ltxtquery</code> ?                   |             |
| <code>ltree[] ?@&gt; ltree → ltree</code><br>Returns first array entry that is an ancestor of <code>ltree</code> , or NULL if none.                                         |             |
| <code>ltree[] ?&lt;@ ltree → ltree</code><br>Returns first array entry that is a descendant of <code>ltree</code> , or NULL if none.                                        |             |
| <code>ltree[] ?~ lquery → ltree</code><br>Returns first array entry that matches <code>lquery</code> , or NULL if none.                                                     |             |
| <code>ltree[] ?@ ltxtquery → ltree</code><br>Returns first array entry that matches <code>ltxtquery</code> , or NULL if none.                                               |             |

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F.13.

**Table F.13. `ltree` Functions**

| Function                                                            | Description                                                                                                                                                                                                                                                                             | Example(s)                                                     |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <code>subltree ( ltree, start integer, end integer ) → ltree</code> | Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0).                                                                                                                                                                | <code>subltree( 'Top.Child1.Child2', 1, 2 ) → Child1</code>    |
| <code>subpath ( ltree, offset integer, len integer ) → ltree</code> | Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path. | <code>subpath( 'Top.Child1.Child2', 0, 2 ) → Top.Child1</code> |
| <code>subpath ( ltree, offset integer ) → ltree</code>              | Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.                                                                                        | <code>subpath( 'Top.Child1.Child2', 1 ) → Child1.Child2</code> |
| <code>nlevel ( ltree ) → integer</code>                             | Returns number of labels in path.                                                                                                                                                                                                                                                       | <code>nlevel( 'Top.Child1.Child2' ) → 3</code>                 |
| <code>index ( a ltree, b ltree ) → integer</code>                   | Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.                                                                                                                                                                                          | <code>index( '0.1.2.3.5.4.5.6.8.5.6.8', '5.6' ) → 6</code>     |
| <code>index ( a ltree, b ltree, offset integer ) → integer</code>   | Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found. The search starts at position <code>offset</code> ; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.                                       | <code>index( '0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4 ) → 9</code> |
| <code>text2ltree ( text ) → ltree</code>                            | Casts <code>text</code> to <code>ltree</code> .                                                                                                                                                                                                                                         |                                                                |
| <code>ltree2text ( ltree ) → text</code>                            | Casts <code>ltree</code> to <code>text</code> .                                                                                                                                                                                                                                         |                                                                |
| <code>lca ( ltree [, ltree [, ... ]] ) → ltree</code>               | Computes longest common ancestor of paths (up to 8 arguments are supported).                                                                                                                                                                                                            | <code>lca( '1.2.3', '1.2.3.4.5.6' ) → 1.2</code>               |
| <code>lca ( ltree[] ) → ltree</code>                                | Computes longest common ancestor of paths in array.                                                                                                                                                                                                                                     | <code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>       |

## F.22.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- Hash index over `ltree`: `=`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines) up to 2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path
gist_ltree_ops(siglen=100));
```

- GiST index over `ltree[]` (`gist__ltree_ops` opclass): `ltree[] <@ ltree, ltree @> ltree[], @, ~, ?`

`gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

## F.22.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES
('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES
('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES
('Top.Collections.Pictures.Astronomy.Astronauts');
```

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
CREATE INDEX path_hash_idx ON test USING HASH (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

We can do inheritance:

```
ltreeest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreeest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreeest=> SELECT path FROM test WHERE path ~ '.*.!
pictures@.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreeest=> SELECT path FROM test WHERE path @ 'Astro*% & !
pictures@';
           path
```

```
-----  
Top.Science.Astronomy  
Top.Science.Astronomy.Astrophysics  
Top.Science.Astronomy.Cosmology  
Top.Hobbies.Amateurs_Astronomy  
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*' & !  
pictures@';  
           path
```

```
-----  
Top.Science.Astronomy  
Top.Science.Astronomy.Astrophysics  
Top.Science.Astronomy.Cosmology  
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM  
test WHERE path <@ 'Top.Science.Astronomy';  
           ?column?
```

```
-----  
Top.Science.Space.Astronomy  
Top.Science.Space.Astronomy.Astrophysics  
Top.Science.Space.Astronomy.Cosmology  
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree  
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'  
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path  
<@ 'Top.Science.Astronomy';  
           ins_label
```

```
-----  
Top.Science.Space.Astronomy  
Top.Science.Space.Astronomy.Astrophysics  
Top.Science.Space.Astronomy.Cosmology  
(3 rows)
```

## F.22.5. Transforms

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

## F.22.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

## F.23. pageinspect — low-level inspection of database pages

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

### F.23.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. *fork* should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all PostgreSQL heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn    | checksum | flags | lower | upper | special |
-----+-----+-----+-----+-----+-----+
0/24A1B50 |          | 0     | 1     | 232   | 368     | 8192 |
8192 |          | 4     | 0
```

The returned columns correspond to the fields in the `PageHeaderData` struct. See `src/include/storage/bufpage.h` for details.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are disabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
        13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm',
0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

See `src/backend/storage/freespace/README` for more information on the structure of an FSM page.

## F.23.2. Heap Functions

`heap_page_items(page bytea)` returns `setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class',
0));
```

See `src/include/storage/itemid.h` and `src/include/access/htup_details.h` for explanations of the fields returned.

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns `bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass,
t_data, t_infomask, t_infomask2, t_bits) FROM
heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is `true`, attributes will be detoasted as needed. Default value is `false`.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns `setof record`

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is `false` by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM
heap_page_item_attrs(get_raw_page('pg_class', 0),
'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)`  
returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
FROM heap_page_items(get_raw_page('pg_class', 0)),
LATERAL heap_tuple_infomask_flags(t_infomask,
t_infomask2)
WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT
NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

See `src/include/access/htup_details.h` for explanations of the flag names returned.

## F.23.3. B-Tree Functions

`bt_metap(relname text)` returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic                | 340322
version              | 4
root                 | 1
level                | 0
fastroot             | 1
fastlevel            | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples | 230
allequalimage        | f
```

`bt_page_stats(relname text, blkno bigint)` returns record

`bt_page_stats` returns summary information about a data page of a B-tree index. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]+-----
blkno         | 1
type          | l
live_items    | 224
dead_items    | 0
```

|               |  |      |
|---------------|--|------|
| avg_item_size |  | 16   |
| page_size     |  | 8192 |
| free_size     |  | 3668 |
| btpo_prev     |  | 0    |
| btpo_next     |  | 0    |
| btpo_level    |  | 0    |
| btpo_flags    |  | 3    |

`bt_multi_page_stats(relname text, blkno bigint, blk_count bigint)`  
returns setof record

`bt_multi_page_stats` returns the same information as `bt_page_stats`, but does so for each page of the range of pages beginning at *blkno* and extending for *blk\_count* pages. If *blk\_count* is negative, all pages from *blkno* to the end of the index are reported on. For example:

```
test=# SELECT * FROM bt_multi_page_stats('pg_proc_oid_index', 5,
2);
-[ RECORD 1 ]-+-----
blkno          | 5
type           | l
live_items     | 367
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 808
btpo_prev      | 4
btpo_next      | 6
btpo_level     | 0
btpo_flags     | 1
-[ RECORD 2 ]-+-----
blkno          | 6
type           | l
live_items     | 367
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 808
btpo_prev      | 5
btpo_next      | 7
btpo_level     | 0
btpo_flags     | 1
```

`bt_page_items(relname text, blkno bigint)` returns setof record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data,
dead, htid, tids[0:2] AS some_tids
FROM bt_page_items('tenk2_hundred', 5);
 itemoffset | ctid | itemlen | nulls | vars | data |
            | dead | htid | some_tids |
-----+-----+-----+-----+-----+-----+
1 | (16,1) | 16 | f | f | 30 00 00 00 |
00 00 00 00 | | | | |
```

```

      2 | (16,8292) |      616 | f      | f      | 24 00 00 00
00 00 00 00 | f      | (1,6)  | {"(1,6)","(10,22)"}
      3 | (16,8292) |      616 | f      | f      | 25 00 00 00
00 00 00 00 | f      | (1,18) | {"(1,18)","(4,22)"}
      4 | (16,8292) |      616 | f      | f      | 26 00 00 00
00 00 00 00 | f      | (4,18) | {"(4,18)","(6,17)"}
      5 | (16,8292) |      616 | f      | f      | 27 00 00 00
00 00 00 00 | f      | (1,2)  | {"(1,2)","(1,19)"}
      6 | (16,8292) |      616 | f      | f      | 28 00 00 00
00 00 00 00 | f      | (2,24) | {"(2,24)","(4,11)"}
      7 | (16,8292) |      616 | f      | f      | 29 00 00 00
00 00 00 00 | f      | (2,17) | {"(2,17)","(11,2)"}
      8 | (16,8292) |      616 | f      | f      | 2a 00 00 00
00 00 00 00 | f      | (0,25) | {"(0,25)","(3,20)"}
      9 | (16,8292) |      616 | f      | f      | 2b 00 00 00
00 00 00 00 | f      | (0,10) | {"(0,10)","(0,14)"}
     10 | (16,8292) |      616 | f      | f      | 2c 00 00 00
00 00 00 00 | f      | (1,3)  | {"(1,3)","(3,9)"}
     11 | (16,8292) |      616 | f      | f      | 2d 00 00 00
00 00 00 00 | f      | (6,28) | {"(6,28)","(11,1)"}
     12 | (16,8292) |      616 | f      | f      | 2e 00 00 00
00 00 00 00 | f      | (0,27) | {"(0,27)","(1,13)"}
     13 | (16,8292) |      616 | f      | f      | 2f 00 00 00
00 00 00 00 | f      | (4,17) | {"(4,17)","(4,21)"}
(13 rows)

```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `bt_po_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see Section 65.1.4.1. For more details about deduplication and posting lists, see Section 65.1.4.3.

`bt_page_items(page bytea)` returns `setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data,
dead, htid, tids[0:2] AS some_tids
FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset | ctid | itemlen | nulls | vars | data
-----+-----+-----+-----+-----+-----
1 | (16,1) | 16 | f | f | 30 00 00 00
00 00 00 00 | | | | |
2 | (16,8292) | 616 | f | f | 24 00 00 00
00 00 00 00 | f | (1,6) | {"(1,6)","(10,22)"}
3 | (16,8292) | 616 | f | f | 25 00 00 00
00 00 00 00 | f | (1,18) | {"(1,18)","(4,22)"}
4 | (16,8292) | 616 | f | f | 26 00 00 00
00 00 00 00 | f | (4,18) | {"(4,18)","(6,17)"}
5 | (16,8292) | 616 | f | f | 27 00 00 00
00 00 00 00 | f | (1,2) | {"(1,2)","(1,19)"}
6 | (16,8292) | 616 | f | f | 28 00 00 00
00 00 00 00 | f | (2,24) | {"(2,24)","(4,11)"}
7 | (16,8292) | 616 | f | f | 29 00 00 00
00 00 00 00 | f | (2,17) | {"(2,17)","(11,2)"}
8 | (16,8292) | 616 | f | f | 2a 00 00 00
00 00 00 00 | f | (0,25) | {"(0,25)","(3,20)"}
9 | (16,8292) | 616 | f | f | 2b 00 00 00

(13 rows)
```

All the other details are the same as explained in the previous item.

## F.23.4. BRIN Functions

`brin_page_type(page bytea)` returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
brin_page_type
-----
meta
```

`brin_metapage_info(page bytea)` returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx',
0));
 magic | version | pagesperpage | lastrevmappage
```

```
-----+-----+-----+-----
0xA8109CFA |      1 |      4 |      2
```

`brin_revmap_data(page bytea)` returns setof `tid`

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx',
2)) LIMIT 5;
 pages
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

`brin_page_items(page bytea, index oid)` returns setof `record`

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls |
placeholder | empty  | value
-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
| f      137 |      0 |      1 | t        | f        | f
| f      137 |      0 |      2 | f        | f        | f
| f      | {1 .. 88}
| f      138 |      4 |      1 | t        | f        | f
| f      138 |      4 |      2 | f        | f        | f
| f      | {89 .. 176}
| f      139 |      8 |      1 | t        | f        | f
| f      139 |      8 |      2 | f        | f        | f
| f      | {177 .. 264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs. See `src/include/access/brin_tuple.h` for details.

## F.23.5. GIN Functions

`gin_metapage_info(page bytea)` returns `record`

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index',
0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
```

```
n_pending_pages | 0
n_pending_tuples | 0
n_total_pages | 7
n_entry_pages | 6
n_data_pages | 0
n_entries | 693
version | 2
```

`gin_page_opaque_info(page bytea)` returns record

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM
      gin_page_opaque_info(get_raw_page('gin_index', 2));
rightlink | maxoff | flags
-----+-----+-----
          5 |          0 | {data, leaf, compressed}
(1 row)
```

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a compressed GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
      FROM gin_leafpage_items(get_raw_page('gin_test_idx',
      2));
first_tid | nbytes | some_tids
-----+-----+-----
(8,41) | 244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45) | 248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52) | 248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59) | 320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16) | 376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30) | 376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44) | 197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

## F.23.6. GiST Functions

`gist_page_opaque_info(page bytea)` returns record

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM
      gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
```

```

lsn | nsn | rightlink | flags
-----+-----+-----+-----
0/1 | 0/0 |          1 | {leaf}
(1 row)

```

`gist_page_items(page bytea, index_oid regclass)` returns setof record

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```

test=# SELECT * FROM
gist_page_items(get_raw_page('test_gist_idx', 0),
'test_gist_idx');
 itemoffset |   ctid   | itemlen | dead | keys
-----+-----+-----+-----+-----
1 | (1,65535) |    40 | f | (p)=("(185,185),
(1,1)")
2 | (2,65535) |    40 | f | (p)=("(370,370),
(186,186)")
3 | (3,65535) |    40 | f | (p)=("(555,555),
(371,371)")
4 | (4,65535) |    40 | f | (p)=("(740,740),
(556,556)")
5 | (5,65535) |    40 | f | (p)=("(870,870),
(741,741)")
6 | (6,65535) |    40 | f | (p)=("(1000,1000),
(871,871)")
(6 rows)

```

`gist_page_items_bytea(page bytea)` returns setof record

Same as `gist_page_items`, but returns the key data as a raw bytea blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```

test=# SELECT * FROM
gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset |   ctid   | itemlen | dead | key_data
-----+-----+-----+-----+-----
1 | (1,65535) |    40 | f | \x00000100ffff280000000000000c064400000000
00c06440000000000000f03f000000000000f03f
2 | (2,65535) |    40 | f | \x00000200ffff280000000000000c074400000000
00c074400000000000e0644000000000e06440
3 | (3,65535) |    40 | f | \x00000300ffff280000000000000207f400000000
00207f400000000000d0744000000000d07440
4 | (4,65535) |    40 | f | \x00000400ffff280000000000000c084400000000
00c08440000000000307f40000000000307f40
5 | (5,65535) |    40 | f | \x00000500ffff28000000000000f089400000000
00f08940000000000c8844000000000c88440

```

```

        6 | (6,65535) |      40 | f      |
\ x000000600ffff2800000000000000208f4000000000
00208f40000000000000f889400000000000f88940
        7 | (7,65535) |      40 | f      |
\ x00000700ffff28000000000000408f4000000000
00408f400000000000288f400000000000288f40
(7 rows)

```

## F.23.7. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```

test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage

```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```

test=# SELECT * FROM
 hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket    | 0
hasho_flag      | 66
hasho_page_id   | 65408

```

`hash_page_items(page bytea)` returns setof record

`hash_page_items` returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```

test=# SELECT * FROM
 hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid   | data
-----+-----+-----
          1 | (899,77) | 1053474816
          2 | (897,29) | 1053474816
          3 | (894,207)| 1053474816
          4 | (892,159)| 1053474816
          5 | (890,111)| 1053474816

```

`hash_bitmap_info(index oid, blkno bigint)` returns record

`hash_bitmap_info` shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
          65 |          3 | t
```

hash\_metapage\_info(page bytea) returns record

hash\_metapage\_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize,
bmshift,
test-#      maxbucket, highmask, lowmask, ovflpoint, firstfree,
test-#      nmaps, procid,
test-#      regexp_replace(spares::text, '(,0)*}', '{}') as
test-#      spares,
test-#      regexp_replace(mapp::text, '(,0)*}', '{}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index',
0));
-[ RECORD 1 ]-----
 magic      | 105121344
 version    | 4
 ntuples    | 500500
 ffactor    | 40
 bsize      | 8152
 bmsize     | 4096
 bmshift    | 15
 maxbucket  | 12512
 highmask   | 16383
 lowmask    | 8191
 ovflpoint  | 28
 firstfree  | 1204
 nmaps      | 1
 procid     | 450
 spares     | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
508,567,628,704,1193,1202,1204}
 mapp       | {65}
```

## F.24. passwordcheck — verify password strength

The `passwordcheck` module checks users' passwords whenever they are set with `CREATE ROLE` or `ALTER ROLE`. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add `'$libdir/passwordcheck'` to `shared_preload_libraries` in `postgresql.conf`, then restart the server.

You can adapt this module to your needs by changing the source code. For example, you can use `CrackLib`<sup>2</sup> to check passwords — this only requires uncommenting two lines in the `Makefile` and rebuilding the module. (We cannot include `CrackLib` by default for license reasons.) Without `CrackLib`, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

### Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, PostgreSQL allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 20) than to rely on passwords within the database.

Alternatively, you could modify `passwordcheck` to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.

### F.24.1. Configuration Parameters

`passwordcheck.min_password_length` (integer)

The minimum acceptable password length in bytes. The default is 8. Only superusers can change this setting.

### Note

This parameter has no effect if a user supplies a pre-encrypted password.

In ordinary usage, this parameter is set in `postgresql.conf`, but superusers can alter it on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
passwordcheck.min_password_length = 12
```

---

<sup>2</sup> <https://github.com/cracklib/cracklib>

## F.25. pg\_buffercache — inspect PostgreSQL buffer cache state

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time. It also offers a low-level way to evict data from it, for testing purposes.

This module provides the `pg_buffercache_pages()` function (wrapped in the `pg_buffercache` view), the `pg_buffercache_numa_pages()` function (wrapped in the `pg_buffercache_numa` view), the `pg_buffercache_summary()` function, the `pg_buffercache_usage_counts()` function, the `pg_buffercache_evict()` function, the `pg_buffercache_evict_relation()` function and the `pg_buffercache_evict_all()` function.

The `pg_buffercache_pages()` function returns a set of records, each row describing the state of one shared buffer entry. The `pg_buffercache` view wraps the function for convenient use.

The `pg_buffercache_numa_pages()` function provides NUMA node mappings for shared buffer entries. This information is not part of `pg_buffercache_pages()` itself, as it is much slower to retrieve. The `pg_buffercache_numa` view wraps the function for convenient use.

The `pg_buffercache_summary()` function returns a single row summarizing the state of the shared buffer cache.

The `pg_buffercache_usage_counts()` function returns a set of records, each row describing the number of buffers with a given usage count.

By default, use of the above functions is restricted to superusers and roles with privileges of the `pg_monitor` role. Access may be granted to others using `GRANT`.

The `pg_buffercache_evict()` function allows a block to be evicted from the buffer pool given a buffer identifier. Use of this function is restricted to superusers only.

The `pg_buffercache_evict_relation()` function allows all unpinned shared buffers in the relation to be evicted from the buffer pool given a relation identifier. Use of this function is restricted to superusers only.

The `pg_buffercache_evict_all()` function allows all unpinned shared buffers to be evicted in the buffer pool. Use of this function is restricted to superusers only.

### F.25.1. The pg\_buffercache View

The definitions of the columns exposed by the view are shown in Table F.14.

**Table F.14. pg\_buffercache Columns**

| Column Type                                       | Description                        |
|---------------------------------------------------|------------------------------------|
| bufferid integer                                  | ID, in the range 1..shared_buffers |
| relfilenode oid (references pg_class.relfilenode) | Filenode number of the relation    |
| reltablespace oid (references pg_tablespace.oid)  | Tablespace OID of the relation     |
| reldatabase oid (references pg_database.oid)      | Database OID of the relation       |
| relforknumber smallint                            |                                    |

| Column Type                                        | Description                                                        |
|----------------------------------------------------|--------------------------------------------------------------------|
|                                                    | Fork number within the relation; see <code>common/relpath.h</code> |
| <code>relblocknumber</code> <code>bigint</code>    | Page number within the relation                                    |
| <code>isdirty</code> <code>boolean</code>          | Is the page dirty?                                                 |
| <code>usagecount</code> <code>smallint</code>      | Clock-sweep access count                                           |
| <code>pinning_backends</code> <code>integer</code> | Number of backends pinning this buffer                             |

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `relatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

## F.25.2. The `pg_buffercache_numa` View

The definitions of the columns exposed by the view are shown in Table F.15.

**Table F.15. `pg_buffercache_numa` Columns**

| Column Type                                  | Description                                      |
|----------------------------------------------|--------------------------------------------------|
| <code>bufferid</code> <code>integer</code>   | ID, in the range 1.. <code>shared_buffers</code> |
| <code>os_page_num</code> <code>bigint</code> | number of OS memory page for this buffer         |
| <code>numa_node</code> <code>int</code>      | ID of NUMA node                                  |

As NUMA node ID inquiry for each page requires memory pages to be paged-in, the first execution of this function can take a noticeable amount of time. In all the cases (first execution or not), retrieving this information is costly and querying the view at a high frequency is not recommended.

### Warning

When determining the NUMA node, the view touches all memory pages for the shared memory segment. This will force allocation of the shared memory, if it wasn't allocated already, and the memory may get allocated in a single NUMA node (depending on system configuration).

## F.25.3. The `pg_buffercache_summary()` Function

The definitions of the columns exposed by the function are shown in Table F.16.

**Table F.16. `pg_buffercache_summary()` Output Columns**

| Column Type<br>Description                                                       |
|----------------------------------------------------------------------------------|
| <code>buffers_used</code> int4<br>Number of used shared buffers                  |
| <code>buffers_unused</code> int4<br>Number of unused shared buffers              |
| <code>buffers_dirty</code> int4<br>Number of dirty shared buffers                |
| <code>buffers_pinned</code> int4<br>Number of pinned shared buffers              |
| <code>usagecount_avg</code> float8<br>Average usage count of used shared buffers |

The `pg_buffercache_summary()` function returns a single row summarizing the state of all shared buffers. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_summary()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_summary()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

## F.25.4. The `pg_buffercache_usage_counts()` Function

The definitions of the columns exposed by the function are shown in Table F.17.

**Table F.17. `pg_buffercache_usage_counts()` Output Columns**

| Column Type<br>Description                                                |
|---------------------------------------------------------------------------|
| <code>usage_count</code> int4<br>A possible buffer usage count            |
| <code>buffers</code> int4<br>Number of buffers with the usage count       |
| <code>dirty</code> int4<br>Number of dirty buffers with the usage count   |
| <code>pinned</code> int4<br>Number of pinned buffers with the usage count |

The `pg_buffercache_usage_counts()` function returns a set of rows summarizing the states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_usage_counts()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_usage_counts()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

## F.25.5. The `pg_buffercache_evict()` Function

The `pg_buffercache_evict()` function takes a buffer identifier, as shown in the `bufferid` column of the `pg_buffercache` view. It returns information about whether the buffer was evicted and flushed. The `buffer_evicted` column is true on success, and false if the buffer wasn't valid, if it couldn't be evicted because it was pinned, or if it became dirty again after an attempt to write it out.

The `buffer_flushed` column is true if the buffer was flushed. This does not necessarily mean that buffer was flushed by us, it might be flushed by someone else. The result is immediately out of date upon return, as the buffer might become valid again at any time due to concurrent activity. The function is intended for developer testing only.

## F.25.6. The `pg_buffercache_evict_relation()` Function

The `pg_buffercache_evict_relation()` function is very similar to the `pg_buffercache_evict()` function. The difference is that the `pg_buffercache_evict_relation()` takes a relation identifier instead of buffer identifier. It tries to evict all buffers for all forks in that relation. It returns the number of evicted buffers, flushed buffers and the number of buffers that could not be evicted. Flushed buffers haven't necessarily been flushed by us, they might have been flushed by someone else. The result is immediately out of date upon return, as buffers might immediately be read back in due to concurrent activity. The function is intended for developer testing only.

## F.25.7. The `pg_buffercache_evict_all()` Function

The `pg_buffercache_evict_all()` function is very similar to the `pg_buffercache_evict()` function. The difference is, the `pg_buffercache_evict_all()` function does not take an argument; instead it tries to evict all buffers in the buffer pool. It returns the number of evicted buffers, flushed buffers and the number of buffers that could not be evicted. Flushed buffers haven't necessarily been flushed by us, they might have been flushed by someone else. The result is immediately out of date upon return, as buffers might immediately be read back in due to concurrent activity. The function is intended for developer testing only.

## F.25.8. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                         WHERE datname =
current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;
```

| nspname    | relname                | buffers |

## F.25.9. Authors

Mark Kirkwood <markir@paradise.net.nz>  
Design suggestions: Neil Conway <neilc@samurai.com>  
Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

## F.26. pgcrypto — cryptographic functions

The `pgcrypto` module provides cryptographic functions for PostgreSQL.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

`pgcrypto` requires OpenSSL and won't be installed if OpenSSL support was not selected when PostgreSQL was built.

### F.26.1. General Hashing Functions

#### F.26.1.1. `digest()`

`digest(data text, type text)` returns `bytea`  
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. Moreover, any digest algorithm OpenSSL supports is automatically picked up.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$  
    SELECT encode(digest($1, 'sha1'), 'hex')  
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

#### F.26.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`  
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

### F.26.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA-1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.

4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.18 lists the algorithms supported by the `crypt()` function.

**Table F.18. Supported Algorithms for `crypt()`**

| Algorithm   | Max Password Length | Adaptive? | Salt Bits | Output Length | Description                                                                                                |
|-------------|---------------------|-----------|-----------|---------------|------------------------------------------------------------------------------------------------------------|
| bf          | 72                  | yes       | 128       | 60            | Blowfish-based, variant 2a                                                                                 |
| md5         | unlimited           | no        | 48        | 34            | MD5-based crypt                                                                                            |
| xdes        | 8                   | yes       | 24        | 20            | Extended DES                                                                                               |
| des         | 8                   | no        | 12        | 13            | Original UNIX crypt                                                                                        |
| sha256crypt | unlimited           | yes       | up to 32  | 80            | Adapted from publicly available reference implementation Unix crypt using SHA-256 and SHA-512 <sup>3</sup> |
| sha512crypt | unlimited           | yes       | up to 32  | 123           | Adapted from publicly available reference implementation Unix crypt using SHA-256 and SHA-512 <sup>4</sup> |

### F.26.2.1. `crypt()`

`crypt(password text, salt text)` returns `text`

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch  
FROM ... ;
```

This returns `true` if the entered password is correct.

### F.26.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer])` returns `text`

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5`, `bf`, `sha256crypt` and `sha512crypt`. The last two, `sha256crypt` and `sha512crypt` are modern SHA-2 based password hashes.

<sup>3</sup> <https://www.akkadia.org/drepper/SHA-crypt.txt>

<sup>4</sup> <https://www.akkadia.org/drepper/SHA-crypt.txt>

The *iter\_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter\_count* parameter is omitted, the default iteration count is used. Allowed values for *iter\_count* depend on the algorithm and are shown in Table F.19.

**Table F.19. Iteration Counts for crypt ( )**

| Algorithm                   | Default | Min  | Max       |
|-----------------------------|---------|------|-----------|
| xdes                        | 725     | 1    | 16777215  |
| bf                          | 6       | 4    | 31        |
| sha256crypt,<br>sha512crypt | 5000    | 1000 | 999999999 |

For xdes there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.20 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the crypt-bf entries, the number after a slash is the *iter\_count* parameter of gen\_salt.

The default *iter\_count* for sha256crypt and sha512crypt of 5000 is considered too low for modern hardware, but can be adjusted to generate stronger password hashes. Otherwise both hashes, sha256crypt and sha512crypt are considered safe.

**Table F.20. Hash Algorithm Speeds**

| Algorithm  | Hashes/sec | For [a-z]     | For [A-Za-z0-9] | Duration relative to md5 hash |
|------------|------------|---------------|-----------------|-------------------------------|
| crypt-bf/8 | 1792       | 4 years       | 3927 years      | 100k                          |
| crypt-bf/7 | 3648       | 2 years       | 1929 years      | 50k                           |
| crypt-bf/6 | 7168       | 1 year        | 982 years       | 25k                           |
| crypt-bf/5 | 13504      | 188 days      | 521 years       | 12.5k                         |
| crypt-md5  | 171584     | 15 days       | 41 years        | 1k                            |
| crypt-des  | 23221568   | 157.5 minutes | 108 days        | 7                             |
| sha1       | 37774272   | 90 minutes    | 68 days         | 4                             |
| md5 (hash) | 150085504  | 22.5 minutes  | 17 days         | 1                             |

Notes:

- The machine used is an Intel Mobile Core i3.
- crypt-des and crypt-md5 algorithm numbers are taken from John the Ripper v1.6.38 - test output.
- md5 hash numbers are from mdcrack 1.2.
- sha1 numbers are from lcrack-20031130-beta.
- crypt-bf numbers are taken using a simple program that loops over 1000 8-character passwords. That way the speed with different numbers of iterations can be shown. For reference: john -test shows 13506 loops/sec for crypt-bf/5. (The very small difference in results is in accordance

with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

## F.26.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880<sup>5</sup>) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA-1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

### F.26.3.1. `pgp_sym_encrypt()`

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns  
bytea  
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ])  
returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

### F.26.3.2. `pgp_sym_decrypt()`

---

<sup>5</sup> <https://datatracker.ietf.org/doc/html/rfc4880>

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ])
returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting *bytea* data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.26.3.3. `pgp_pub_encrypt ( )`

```
pgp_pub_encrypt(data text, key bytea [, options text ]) returns
bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ])
returns bytea
```

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

### F.26.3.4. `pgp_pub_decrypt ( )`

```
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options
text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options
text ]]) returns bytea
```

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting *bytea* data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.26.3.5. `pgp_key_id ( )`

```
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- **SYMKEY**

The message is encrypted with a symmetric key.

- **ANYKEY**

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

### F.26.3.6. `armor()`, `dearmor()`

`armor(data bytea [ , keys text[], values text[] ])` returns `text`  
`dearmor(data text)` returns `bytea`

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

### F.26.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns  
`setof record`

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

### F.26.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-cr lf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

#### F.26.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256`, `3des`, `cast5`

Default: `aes128`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.26.3.8.2. `compress-algo`

Which compression algorithm to use. Only available if PostgreSQL was built with `zlib`.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

### **F.26.3.8.3. compress-level**

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

### **F.26.3.8.4. convert-crlf**

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt, pgp\_sym\_decrypt, pgp\_pub\_decrypt

### **F.26.3.8.5. disable-mdc**

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

### **F.26.3.8.6. sess-key**

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt

### **F.26.3.8.7. s2k-mode**

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: pgp\_sym\_encrypt

### **F.26.3.8.8. s2k-count**

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: `pgp_sym_encrypt`, only with `s2k-mode=3`

#### **F.26.3.8.9. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: `md5`, `sha1`

Default: `sha1`

Applies to: `pgp_sym_encrypt`

#### **F.26.3.8.10. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.

Values: `bf`, `aes`, `aes128`, `aes192`, `aes256`

Default: `use cipher-algo`

Applies to: `pgp_sym_encrypt`

#### **F.26.3.8.11. unicode-mode**

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: `0`, `1`

Default: `0`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

### **F.26.3.9. Generating PGP Keys with GnuPG**

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, The GNU Privacy Handbook<sup>6</sup> and other documentation on <https://www.gnupg.org/>.

### F.26.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

## F.26.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea  
decrypt(data bytea, key bytea, type text) returns bytea
```

```
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns  
bytea  
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns  
bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `cfb` — next block depends on previous encrypted block
- `ecb` — each block is encrypted separately (for testing only)

---

<sup>6</sup> <https://www.gnupg.org/gph/en/manual.html>

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC and CFB mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

## F.26.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the core function of the same name.)

## F.26.6. OpenSSL Support Functions

`fips_mode()` returns `boolean`

Returns `true` if OpenSSL is running with FIPS mode enabled, otherwise `false`.

## F.26.7. Configuration Parameters

There is one configuration parameter that controls the behavior of `pgcrypto`.

`pgcrypto.builtin_crypto_enabled` (enum)

`pgcrypto.builtin_crypto_enabled` determines if the built in crypto functions `gen_salt()`, and `crypt()` are available for use. Setting this to `off` disables these functions. `on` (the default) enables these functions to work normally. `fips` disables these functions if OpenSSL is detected to operate in FIPS mode.

In ordinary usage, this parameter is set in `postgresql.conf`, although superusers can alter it on-the-fly within their own sessions.

## F.26.8. Notes

### F.26.8.1. Configuration

`pgcrypto` configures itself according to the findings of the main PostgreSQL `configure` script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

`pgcrypto` requires OpenSSL. Otherwise, it will not be built or installed.

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

## F.26.8.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

## F.26.8.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacks<sup>7</sup>. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

## F.26.9. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

| Algorithm      | Author                  | Source origin    |
|----------------|-------------------------|------------------|
| DES crypt      | David Burren and others | FreeBSD libcrypt |
| MD5 crypt      | Poul-Henning Kamp       | FreeBSD libcrypt |
| Blowfish crypt | Solar Designer          | www.openwall.com |

---

<sup>7</sup> [https://en.wikipedia.org/wiki/Side-channel\\_attack](https://en.wikipedia.org/wiki/Side-channel_attack)

## F.27. pg\_freespacemap — examine the free space map

The `pg_freespacemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and roles with privileges of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

### F.27.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

### F.27.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
 blkno | avail 
-----+-----
      0 |      0
      1 |      0
      2 |      0
      3 |     32
      4 |    704
      5 |    704
      6 |    704
      7 |   1216
      8 |    704
      9 |    704
     10 |    704
     11 |    704
     12 |    704
     13 |    704
     14 |    704
     15 |    704
     16 |    704
     17 |    704
     18 |    704
     19 |   3648
(20 rows)
```

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
pg_freespace
-----
          1216
(1 row)
```

### F.27.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

## F.28. pg\_logicalinspect — logical decoding components inspection

The `pg_logicalinspect` module provides SQL functions that allow you to inspect the contents of logical decoding components. It allows the inspection of serialized logical snapshots of a running PostgreSQL database cluster, which is useful for debugging or educational purposes.

By default, use of these functions is restricted to superusers and members of the `pg_read_server_files` role. Access may be granted by superusers to others using `GRANT`.

### F.28.1. Functions

`pg_get_logical_snapshot_meta(filename text)` returns record

Gets logical snapshot metadata about a snapshot file that is located in the server's `pg_logical/snapshots` directory. The *filename* argument represents the snapshot file name. For example:

```
postgres=# SELECT * FROM pg_ls_logicalsnapdir();
-[ RECORD 1 ]+-----
name          | 0-40796E18.snap
size          | 152
modification  | 2024-08-14 16:36:32+00
```

```
postgres=# SELECT * FROM
  pg_get_logical_snapshot_meta('0-40796E18.snap');
-[ RECORD 1 ]-----
magic        | 1369563137
checksum     | 1028045905
version      | 6
```

```
postgres=# SELECT ss.name, meta.* FROM pg_ls_logicalsnapdir() AS
  ss,
  pg_get_logical_snapshot_meta(ss.name) AS meta;
-[ RECORD 1 ]-----
name          | 0-40796E18.snap
magic         | 1369563137
checksum      | 1028045905
version       | 6
```

If *filename* does not match a snapshot file, the function raises an error.

`pg_get_logical_snapshot_info(filename text)` returns record

Gets logical snapshot information about a snapshot file that is located in the server's `pg_logical/snapshots` directory. The *filename* argument represents the snapshot file name. For example:

```
postgres=# SELECT * FROM pg_ls_logicalsnapdir();
-[ RECORD 1 ]+-----
name          | 0-40796E18.snap
size          | 152
modification  | 2024-08-14 16:36:32+00
```

```
postgres=# SELECT * FROM
pg_get_logical_snapshot_info('0-40796E18.snap');
-[ RECORD 1 ]-----+-----
state           | consistent
xmin            | 751
xmax            | 751
start_decoding_at | 0/40796AF8
two_phase_at    | 0/40796AF8
initial_xmin_horizon | 0
building_full_snapshot | f
in_slot_creation | f
last_serialized_snapshot | 0/0
next_phase_at   | 0
committed_count | 0
committed_xip   | 
catchange_count | 2
catchange_xip   | {751,752}
```

```
postgres=# SELECT ss.name, info.* FROM pg_ls_logicalsnapdir() AS
ss,
pg_get_logical_snapshot_info(ss.name) AS info;
-[ RECORD 1 ]-----+-----
name           | 0-40796E18.snap
state           | consistent
xmin            | 751
xmax            | 751
start_decoding_at | 0/40796AF8
two_phase_at    | 0/40796AF8
initial_xmin_horizon | 0
building_full_snapshot | f
in_slot_creation | f
last_serialized_snapshot | 0/0
next_phase_at   | 0
committed_count | 0
committed_xip   | 
catchange_count | 2
catchange_xip   | {751,752}
```

If *filename* does not match a snapshot file, the function raises an error.

## F.29. pg\_overexplain — allow EXPLAIN to dump even more details

The `pg_overexplain` module extends `EXPLAIN` with new options that provide additional output. It is mostly intended to assist with debugging of and development of the planner, rather than for general use. Since this module displays internal details of planner data structures, it may be necessary to refer to the source code to make sense of the output. Furthermore, the output is likely to change whenever (and as often as) those data structures change.

To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'pg_overexplain';
```

You can also preload it into some or all sessions by including `pg_overexplain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`.

### F.29.1. EXPLAIN (DEBUG)

The `DEBUG` option displays miscellaneous information from the plan tree that is not normally shown because it is not expected to be of general interest. For each individual plan node, it will display the following fields. See `Plan` in `nodes/plannodes.h` for additional documentation of these fields.

- **Disabled Nodes.** Normal `EXPLAIN` determines whether a node is disabled by checking whether the node's count of disabled nodes is larger than the sum of the counts for the underlying nodes. This option shows the raw counter value.
- **Parallel Safe.** Indicates whether it would be safe for a plan tree node to appear beneath a `Gather` or `Gather Merge` node, regardless of whether it is actually below such a node.
- **Plan Node ID.** An internal ID number that should be unique for every node in the plan tree. It is used to coordinate parallel query activity.
- **extParam and allParam.** Information about which numbered parameters affect this plan node or its children. In text mode, these fields are only displayed if they are non-empty sets.

Once per query, the `DEBUG` option will display the following fields. See `PlannedStmt` in `nodes/plannodes.h` for additional detail.

- **Command Type.** For example, `select` or `update`.
- **Flags.** A comma-separated list of Boolean structure member names from the `PlannedStmt` that are set to `true`. It covers the following structure members: `hasReturning`, `hasModifyingCTE`, `canSetTag`, `transientPlan`, `dependsOnRole`, `parallelModeNeeded`.
- **Subplans Needing Rewind.** Integer IDs of subplans that may need to be rewound by the executor.
- **Relation OIDs.** OIDs of relations upon which this plan depends.
- **Executor Parameter Types.** Type OID for each executor parameter (e.g. when a nested loop is chosen and a parameter is used to pass a value down to an inner index scan). Does not include parameters supplied to a prepared statement by the user.
- **Parse Location.** Location within the query string supplied to the planner where this query's text can be found. May be `Unknown` in some contexts. Otherwise, may be `NNN to end` for some integer `NNN` or `NNN for MMM bytes` for some integers `NNN` and `MMM`.

## F.29.2. EXPLAIN (RANGE\_TABLE)

The `RANGE_TABLE` option displays information from the plan tree specifically concerning the query's range table. Range table entries correspond roughly to items appearing in the query's `FROM` clause, but with numerous exceptions. For example, subqueries that are proved unnecessary may be deleted from the range table entirely, while inheritance expansion adds range table entries for child tables that are not named directly in the query.

Range table entries are generally referenced within the query plan by a range table index, or RTI. Plan nodes that reference one or more RTIs will be labelled accordingly, using one of the following fields: `Scan RTI`, `Nominal RTI`, `Exclude Relation RTI`, `Append RTIs`.

In addition, the query as a whole may maintain lists of range table indexes that are needed for various purposes. These lists will be displayed once per query, labelled as appropriate as `Unprunable RTIs` or `Result RTIs`. In text mode, these fields are only displayed if they are non-empty sets.

Finally, but most importantly, the `RANGE_TABLE` option will display a dump of the query's entire range table. Each range table entry is labelled with the appropriate range table index, the kind of range table entry (e.g. `relation`, `subquery`, or `join`), followed by the contents of various range table entry fields that are not normally part of `EXPLAIN` output. Some of these fields are only displayed for certain kinds of range table entries. For example, `Eref` is displayed for all types of range table entries, but `CTE Name` is displayed only for range table entries of type `cte`.

For more information about range table entries, see the definition of `RangeTblEntry` in `nodes/parsenodes.h`.

Robert Haas <rhaas@postgresql.org>

## F.30. pg\_prewarm — preload relation data into buffer caches

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the PostgreSQL buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in `shared_preload_libraries`. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

### F.30.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default  
    'main',  
            first_block int8 default null,  
            last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by PostgreSQL when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

### F.30.2. Configuration Parameters

```
pg_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

`pg_prewarm.autoprewarm_interval`(integer)

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

## F.30.3. Author

Robert Haas <[rhaas@postgresql.org](mailto:rhaas@postgresql.org)>

## F.31. pgrowlocks — show a table's row locking information

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, roles with privileges of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

### F.31.1. Overview

`pgrowlocks(text)` returns `setof record`

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.21.

**Table F.21. `pgrowlocks` Output Columns**

| Name                    | Type                   | Description                                                                                                                                                                                                                               |
|-------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>locked_row</code> | <code>tid</code>       | Tuple ID (TID) of locked row                                                                                                                                                                                                              |
| <code>locker</code>     | <code>xid</code>       | Transaction ID of locker, or multixact ID if multitransaction; see Section 67.1                                                                                                                                                           |
| <code>multi</code>      | <code>boolean</code>   | True if locker is a multitransaction                                                                                                                                                                                                      |
| <code>xids</code>       | <code>xid[]</code>     | Transaction IDs of lockers (more than one if multitransaction)                                                                                                                                                                            |
| <code>modes</code>      | <code>text[]</code>    | Lock mode of lockers (more than one if multitransaction), an array of <code>For Key Share</code> , <code>For Share</code> , <code>For No Key Update</code> , <code>No Key Update</code> , <code>For Update</code> , <code>Update</code> . |
| <code>pids</code>       | <code>integer[]</code> | Process IDs of locking backends (more than one if multitransaction)                                                                                                                                                                       |

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

## F.31.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      |      609 | f      | {609} | {"For Share"} | {3161}
(0,2)      |      609 | f      | {609} | {"For Share"} | {3161}
(0,3)      |      607 | f      | {607} | {"For Update"} | {3107}
(0,4)      |      607 | f      | {607} | {"For Update"} | {3107}
(4 rows)
```

## F.32. pg\_stat\_statements — track statistics of SQL planning and execution

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if `compute_query_id` is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

When `pg_stat_statements` is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views `pg_stat_statements` and `pg_stat_statements_info`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

### F.32.1. The pg\_stat\_statements View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.22.

**Table F.22. pg\_stat\_statements Columns**

| Column Type                                                      | Description                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>userid oid</code> (references <code>pg_authid.oid</code> ) | OID of user who executed the statement                                                                                                                                                                                                                                                                                                          |
| <code>dbid oid</code> (references <code>pg_database.oid</code> ) | OID of database in which the statement was executed                                                                                                                                                                                                                                                                                             |
| <code>toplevel bool</code>                                       | True if the query was executed as a top-level statement (always true if <code>pg_stat_statements.track</code> is set to <code>top</code> )                                                                                                                                                                                                      |
| <code>queryid bigint</code>                                      | Hash code to identify identical normalized queries.                                                                                                                                                                                                                                                                                             |
| <code>query text</code>                                          | Text of a representative statement                                                                                                                                                                                                                                                                                                              |
| <code>plans bigint</code>                                        | Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                                                                        |
| <code>total_plan_time double precision</code>                    | Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                                                         |
| <code>min_plan_time double precision</code>                      | Minimum time spent planning the statement, in milliseconds. This field will be zero if <code>pg_stat_statements.track_planning</code> is disabled, or if the counter has been reset using the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> and never been planned since. |
| <code>max_plan_time double precision</code>                      |                                                                                                                                                                                                                                                                                                                                                 |

| Column Type                                    | Description                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                | Maximum time spent planning the statement, in milliseconds. This field will be zero if <code>pg_stat_statements.track_planning</code> is disabled, or if the counter has been reset using the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> and never been planned since. |
| <code>mean_plan_time</code> double precision   | Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                                                          |
| <code>stddev_plan_time</code> double precision | Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                              |
| <code>calls</code> bigint                      | Number of times the statement was executed                                                                                                                                                                                                                                                                                                      |
| <code>total_exec_time</code> double precision  | Total time spent executing the statement, in milliseconds                                                                                                                                                                                                                                                                                       |
| <code>min_exec_time</code> double precision    | Minimum time spent executing the statement, in milliseconds, this field will be zero until this statement is executed first time after reset performed by the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code>                                                               |
| <code>max_exec_time</code> double precision    | Maximum time spent executing the statement, in milliseconds, this field will be zero until this statement is executed first time after reset performed by the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code>                                                               |
| <code>mean_exec_time</code> double precision   | Mean time spent executing the statement, in milliseconds                                                                                                                                                                                                                                                                                        |
| <code>stddev_exec_time</code> double precision | Population standard deviation of time spent executing the statement, in milliseconds                                                                                                                                                                                                                                                            |
| <code>rows</code> bigint                       | Total number of rows retrieved or affected by the statement                                                                                                                                                                                                                                                                                     |
| <code>shared_blks_hit</code> bigint            | Total number of shared block cache hits by the statement                                                                                                                                                                                                                                                                                        |
| <code>shared_blks_read</code> bigint           | Total number of shared blocks read by the statement                                                                                                                                                                                                                                                                                             |
| <code>shared_blks_dirtied</code> bigint        | Total number of shared blocks dirtied by the statement                                                                                                                                                                                                                                                                                          |
| <code>shared_blks_written</code> bigint        | Total number of shared blocks written by the statement                                                                                                                                                                                                                                                                                          |
| <code>local_blks_hit</code> bigint             | Total number of local block cache hits by the statement                                                                                                                                                                                                                                                                                         |
| <code>local_blks_read</code> bigint            | Total number of local blocks read by the statement                                                                                                                                                                                                                                                                                              |
| <code>local_blks_dirtied</code> bigint         | Total number of local blocks dirtied by the statement                                                                                                                                                                                                                                                                                           |
| <code>local_blks_written</code> bigint         | Total number of local blocks written by the statement                                                                                                                                                                                                                                                                                           |
| <code>temp_blks_read</code> bigint             | Total number of temp blocks read by the statement                                                                                                                                                                                                                                                                                               |
| <code>temp_blks_written</code> bigint          | Total number of temp blocks written by the statement                                                                                                                                                                                                                                                                                            |

| <b>Column Type</b>                                  | <b>Description</b>                                                                                                                         |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shared_blk_read_time</code> double precision  | Total time the statement spent reading shared blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)         |
| <code>shared_blk_write_time</code> double precision | Total time the statement spent writing shared blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)         |
| <code>local_blk_read_time</code> double precision   | Total time the statement spent reading local blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)          |
| <code>local_blk_write_time</code> double precision  | Total time the statement spent writing local blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero)          |
| <code>temp_blk_read_time</code> double precision    | Total time the statement spent reading temporary file blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero) |
| <code>temp_blk_write_time</code> double precision   | Total time the statement spent writing temporary file blocks, in milliseconds (if <code>track_io_timing</code> is enabled, otherwise zero) |
| <code>wal_records</code> bigint                     | Total number of WAL records generated by the statement                                                                                     |
| <code>wal_fpi</code> bigint                         | Total number of WAL full page images generated by the statement                                                                            |
| <code>wal_bytes</code> numeric                      | Total amount of WAL generated by the statement in bytes                                                                                    |
| <code>wal_buffers_full</code> bigint                | Number of times the WAL buffers became full                                                                                                |
| <code>jit_functions</code> bigint                   | Total number of functions JIT-compiled by the statement                                                                                    |
| <code>jit_generation_time</code> double precision   | Total time spent by the statement on generating JIT code, in milliseconds                                                                  |
| <code>jit_inlining_count</code> bigint              | Number of times functions have been inlined                                                                                                |
| <code>jit_inlining_time</code> double precision     | Total time spent by the statement on inlining functions, in milliseconds                                                                   |
| <code>jit_optimization_count</code> bigint          | Number of times the statement has been optimized                                                                                           |
| <code>jit_optimization_time</code> double precision | Total time spent by the statement on optimizing, in milliseconds                                                                           |
| <code>jit_emission_count</code> bigint              | Number of times code has been emitted                                                                                                      |
| <code>jit_emission_time</code> double precision     | Total time spent by the statement on emitting code, in milliseconds                                                                        |
| <code>jit_deform_count</code> bigint                | Total number of tuple deform functions JIT-compiled by the statement                                                                       |
| <code>jit_deform_time</code> double precision       | Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds                                                 |
| <code>parallel_workers_to_launch</code> bigint      |                                                                                                                                            |

| Column Type                                              | Description                                                                                                                                                                                         |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                          | Number of parallel workers planned to be launched                                                                                                                                                   |
| <code>parallel_workers_launched</code> bigint            | Number of parallel workers actually launched                                                                                                                                                        |
| <code>stats_since</code> timestamp with time zone        | Time at which statistics gathering started for this statement                                                                                                                                       |
| <code>minmax_stats_since</code> timestamp with time zone | Time at which min/max statistics gathering started for this statement (fields <code>min_plan_time</code> , <code>max_plan_time</code> , <code>min_exec_time</code> and <code>max_exec_time</code> ) |

For security reasons, only superusers and roles with privileges of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`) and utility commands are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query.

### Note

The following details about constant replacement and `queryid` only apply when `compute_query_id` is enabled. If you use an external module instead to compute `queryid`, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

Queries on which normalization can be applied may be observed with constant values in `pg_stat_statements`, especially when there is a high rate of entry deallocations. To reduce the likelihood of this happening, consider increasing `pg_stat_statements.max`. The `pg_stat_statements_info` view, discussed below in Section F.32.2, provides statistics about entry deallocations.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry; as explained above, this is expected to happen for semantically equivalent queries. In addition, if the only difference between queries is the number of elements in a list of constants, the list will get squashed down to a single element but shown with a commented-out list indicator:

```
=# SELECT pg_stat_statements_reset();
=# SELECT * FROM test WHERE a IN (1, 2, 3, 4, 5, 6, 7);
=# SELECT * FROM test WHERE a IN (1, 2, 3, 4, 5, 6, 7, 8);
=# SELECT query, calls FROM pg_stat_statements
   WHERE query LIKE 'SELECT%';
-[ RECORD 1 ]-----
query | SELECT * FROM test WHERE a IN ($1 /*, ... */)
calls | 2
```

In addition to these cases, there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference for example a function that was dropped and recreated between the executions of the two queries. Conversely, if a table is dropped and recreated between the executions of queries, two apparently-identical queries may be considered the same. However, if the alias for a table is different for otherwise-similar queries, these queries will be considered distinct. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of PostgreSQL.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog metadata details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

## F.32.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in Table F.23.

**Table F.23. `pg_stat_statements_info` Columns**

| Column Type<br>Description  |
|-----------------------------|
| <code>dealloc bigint</code> |

| Column Type              | Description                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | Total number of times <code>pg_stat_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pg_stat_statements.max</code> were observed |
| <code>stats_reset</code> | timestamp with time zone<br>Time at which all statistics in the <code>pg_stat_statements</code> view were last reset.                                                                                      |

## F.32.3. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint, minmax_only boolean)` returns timestamp with time zone

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the `pg_stat_statements` view are discarded, it will also reset the statistics in the `pg_stat_statements_info` view. When `minmax_only` is true only the values of minimum and maximum planning and execution time will be reset (i.e. `min_plan_time`, `max_plan_time`, `min_exec_time` and `max_exec_time` fields). The default value for `minmax_only` parameter is false. Time of last min/max reset performed is shown in `minmax_stats_since` field of the `pg_stat_statements` view. This function returns the time of a reset. This time is saved to `stats_reset` field of `pg_stat_statements_info` view or to `minmax_stats_since` field of the `pg_stat_statements` view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the OUT argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

## F.32.4. Configuration Parameters

`pg_stat_statements.max` (integer)

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the `pg_stat_statements_info` view. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track` (enum)

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility` (boolean)

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning` (boolean)

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

## F.32.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

## F.32.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

## F.33. pgstattuple — obtain tuple-level statistics

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.33.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len      | 458752
tuple_count    | 1470
tuple_len      | 438896
tuple_percent  | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space     | 8932
free_percent   | 1.95
```

The output columns are described in Table F.24.

**Table F.24. pgstattuple Output Columns**

| Column                          | Type                | Description                          |
|---------------------------------|---------------------|--------------------------------------|
| <code>table_len</code>          | <code>bigint</code> | Physical relation length in bytes    |
| <code>tuple_count</code>        | <code>bigint</code> | Number of live tuples                |
| <code>tuple_len</code>          | <code>bigint</code> | Total length of live tuples in bytes |
| <code>tuple_percent</code>      | <code>float8</code> | Percentage of live tuples            |
| <code>dead_tuple_count</code>   | <code>bigint</code> | Number of dead tuples                |
| <code>dead_tuple_len</code>     | <code>bigint</code> | Total length of dead tuples in bytes |
| <code>dead_tuple_percent</code> | <code>float8</code> | Percentage of dead tuples            |
| <code>free_space</code>         | <code>bigint</code> | Total free space in bytes            |
| <code>free_percent</code>       | <code>float8</code> | Percentage of free space             |

#### Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead,

the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version          | 2
tree_level       | 0
index_size       | 16384
root_block_no    | 1
internal_pages   | 0
leaf_pages       | 1
empty_pages      | 0
deleted_pages    | 0
avg_leaf_density | 54.27
leaf_fragmentation | 0
```

The output columns are:

| Column             | Type    | Description                              |
|--------------------|---------|------------------------------------------|
| version            | integer | B-tree version number                    |
| tree_level         | integer | Tree level of the root page              |
| index_size         | bigint  | Total index size in bytes                |
| root_block_no      | bigint  | Location of root page (zero if none)     |
| internal_pages     | bigint  | Number of “internal” (upper-level) pages |
| leaf_pages         | bigint  | Number of leaf pages                     |
| empty_pages        | bigint  | Number of empty pages                    |
| deleted_pages      | bigint  | Number of deleted pages                  |
| avg_leaf_density   | float8  | Average density of leaf pages            |
| leaf_fragmentation | float8  | Leaf page fragmentation                  |

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]-----
version          | 1
pending_pages    | 0
pending_tuples   | 0
```

The output columns are:

| Column         | Type    | Description                          |
|----------------|---------|--------------------------------------|
| version        | integer | GIN version number                   |
| pending_pages  | integer | Number of pages in the pending list  |
| pending_tuples | bigint  | Number of tuples in the pending list |

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]-----
version          | 4
bucket_pages     | 33081
overflow_pages   | 0
bitmap_pages     | 1
unused_pages     | 32455
live_items       | 10204006
dead_items       | 0
free_percent     | 61.8005949100872
```

The output columns are:

| Column         | Type    | Description              |
|----------------|---------|--------------------------|
| version        | integer | HASH version number      |
| bucket_pages   | bigint  | Number of bucket pages   |
| overflow_pages | bigint  | Number of overflow pages |
| bitmap_pages   | bigint  | Number of bitmap pages   |
| unused_pages   | bigint  | Number of unused pages   |
| live_items     | bigint  | Number of live tuples    |
| dead_tuples    | bigint  | Number of dead tuples    |
| free_percent   | float   | Percentage of free space |

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns `bigint`

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as `TEXT`. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns `record`

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM
       pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len      | 573440
scanned_percent | 2
approx_tuple_count | 2740
approx_tuple_len | 561210
approx_tuple_percent | 97.87
dead_tuple_count | 0
dead_tuple_len  | 0
dead_tuple_percent | 0
approx_free_space | 11996
approx_free_percent | 2.09
```

The output columns are described in Table F.25.

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.reltuples`).

**Table F.25. `pgstattuple_approx` Output Columns**

| Column                            | Type                | Description                                      |
|-----------------------------------|---------------------|--------------------------------------------------|
| <code>table_len</code>            | <code>bigint</code> | Physical relation length in bytes (exact)        |
| <code>scanned_percent</code>      | <code>float8</code> | Percentage of table scanned                      |
| <code>approx_tuple_count</code>   | <code>bigint</code> | Number of live tuples (estimated)                |
| <code>approx_tuple_len</code>     | <code>bigint</code> | Total length of live tuples in bytes (estimated) |
| <code>approx_tuple_percent</code> | <code>float8</code> | Percentage of live tuples                        |
| <code>dead_tuple_count</code>     | <code>bigint</code> | Number of dead tuples (exact)                    |
| <code>dead_tuple_len</code>       | <code>bigint</code> | Total length of dead tuples in bytes (exact)     |

| Column              | Type   | Description                           |
|---------------------|--------|---------------------------------------|
| dead_tuple_percent  | float8 | Percentage of dead tuples             |
| approx_free_space   | bigint | Total free space in bytes (estimated) |
| approx_free_percent | float8 | Percentage of free space              |

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

## F.33.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

## F.34. pg\_surgery — perform low-level surgery on relation data

The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause `UNIQUE` or `FOREIGN KEY` constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

### F.34.1. Functions

`heap_force_kill(regclass, tid[])` returns void

`heap_force_kill` marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or
         directory.
```

```
test=# select heap_force_kill('t1'::regclass, ARRAY['(0,
1)']::tid[]);
heap_force_kill
```

```
-----
```

```
(1 row)
```

```
test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

`heap_force_freeze(regclass, tid[])` returns void

`heap_force_freeze` marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"
```

```
test=# select ctid from t1 where xmin = 507;
       ctid
```

```
-----
```

```
(0,3)
```

```
(1 row)
```

```
test=# select heap_force_freeze('t1'::regclass, ARRAY['(0,
3)']::tid[]);
heap_force_freeze
```

```
-----
```

(1 row)

```
test=# select ctid from t1 where xmin = 2;
      ctid
-----
(0,3)
(1 row)
```

## F.34.2. Authors

Ashutosh Sharma <ashu.coek88@gmail.com>

## F.35. pg\_trgm — support for similarity of text using trigram matching

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.35.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

#### Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo | bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

### F.35.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in Table F.26, the operators in Table F.27.

**Table F.26. `pg_trgm` Functions**

| Function                                               | Description                                                                                                                                                                                                                                                             |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>similarity(text, text) → real</code>             | Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).                                                  |
| <code>show_trgm(text) → text[]</code>                  | Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)                                                                                                                                                     |
| <code>word_similarity(text, text) → real</code>        | Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.                                           |
| <code>strict_word_similarity(text, text) → real</code> | Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string. |
| <code>show_limit() → real</code>                       | Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be mis-                                                                                    |

| Function                             | Description                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                      | spellings of each other, for example. ( <i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold</code> .)                                                                                                                          |
| <code>set_limit (real) → real</code> | Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. ( <i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold</code> .) |

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
              0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "or-d", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'),
       similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
          0.571429 |    0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

**Table F.27. pg\_trgm Operators**

| Operator                               | Description                                                                                                                                                                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text % text → boolean</code>     | Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .                                                                                                                     |
| <code>text &lt;% text → boolean</code> | Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter. |
| <code>text %&gt; text → boolean</code> |                                                                                                                                                                                                                                                                                           |

| Operator                                        | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                 | Commutator of the <% operator.                                                                                                                                                                                                                                                                                                        |
| <code>text &lt;&lt;% text → boolean</code>      | Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter. |
| <code>text %&gt;&gt; text → boolean</code>      | Commutator of the <<% operator.                                                                                                                                                                                                                                                                                                       |
| <code>text &lt;-&gt; text → real</code>         | Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.                                                                                                                                                                                                                                  |
| <code>text &lt;&lt;-&gt; text → real</code>     | Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.                                                                                                                                                                                                                             |
| <code>text &lt;-&gt;&gt; text → real</code>     | Commutator of the <<-> operator.                                                                                                                                                                                                                                                                                                      |
| <code>text &lt;&lt;&lt;-&gt; text → real</code> | Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.                                                                                                                                                                                                                      |
| <code>text &lt;-&gt;&gt;&gt; text → real</code> | Commutator of the <<<-> operator.                                                                                                                                                                                                                                                                                                     |

## F.35.3. GUC Parameters

`pg_trgm.similarity_threshold (real)`

Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold (real)`

Sets the current word similarity threshold that is used by the <% and %> operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold (real)`

Sets the current strict word similarity threshold that is used by the <<% and %>> operators. The threshold must be between 0 and 1 (default is 0.5).

## F.35.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~`, `~*` and `=` queries. The similarity comparisons are case-insensitive in a default build of `pg_trgm`. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t
gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.35.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM
documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

### Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.36. pg\_visibility — visibility map information and utilities

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

### F.36.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns `setof tid`

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns `setof tid`

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns `void`

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

## F.36.2. Author

Robert Haas <[rhaas@postgresql.org](mailto:rhaas@postgresql.org)>

## F.37. pg\_walinspect — low-level WAL inspection

The `pg_walinspect` module provides SQL functions that allow you to inspect the contents of write-ahead log of a running PostgreSQL database cluster at a low level, which is useful for debugging, analytical, reporting or educational purposes. It is similar to `pg_waldump`, but accessible through SQL rather than a separate utility.

All the functions of this module will provide the WAL information using the server's current timeline ID.

### Note

The `pg_walinspect` functions are often called using an LSN argument that specifies the location at which a known WAL record of interest *begins*. However, some functions, such as `pg_logical_emit_message`, return the LSN *after* the record that was just inserted.

### Tip

All of the `pg_walinspect` functions that show information about records that fall within a certain LSN range are permissive about accepting *end\_lsn* arguments that are after the server's current LSN. Using an *end\_lsn* “from the future” will not raise an error.

It may be convenient to provide the value `FFFFFFFF/FFFFFFFF` (the maximum valid `pg_lsn` value) as an *end\_lsn* argument. This is equivalent to providing an *end\_lsn* argument matching the server's current LSN.

By default, use of these functions is restricted to superusers and members of the `pg_read_server_files` role. Access may be granted by superusers to others using `GRANT`.

### F.37.1. General Functions

`pg_get_wal_record_info(in_lsn pg_lsn)` returns record

Gets WAL record information about a record that is located at or after the *in\_lsn* argument. For example:

```
postgres=# SELECT * FROM pg_get_wal_record_info('0/E419E28');
-[ RECORD 1 ]----
+-----+
start_lsn      | 0/E419E28
end_lsn        | 0/E419E68
prev_lsn       | 0/E419D78
xid            | 0
resource_manager | Heap2
record_type     | VACUUM
record_length   | 58
main_data_length | 2
fpi_length      | 0

                | 364
```

If *in\_lsn* isn't at the start of a WAL record, information about the next valid WAL record is shown instead. If there is no next valid WAL record, the function raises an error.

`pg_get_wal_records_info(start_lsn pg_lsn, end_lsn pg_lsn)` returns  
setof record

Gets information of all the valid WAL records between *start\_lsn* and *end\_lsn*. Returns one row per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_records_info('0/1E913618',
'0/1E913740') LIMIT 1;
-[ RECORD 1 ]----
+-----+
start_lsn      | 0/1E913618
end_lsn        | 0/1E913650
prev_lsn       | 0/1E9135A0
xid            | 0

description     | nextXid 33775 latestCompletedXid 33774
oldestRunningXid | 33775
block_ref      |
```

The function raises an error if *start\_lsn* is not available.

`pg_get_wal_block_info(start_lsn pg_lsn, end_lsn pg_lsn, show_data  
boolean DEFAULT true)` returns setof record

Gets information about each block reference from all the valid WAL records between *start\_lsn* and *end\_lsn* with one or more block references. Returns one row per block reference per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_block_info('0/1230278',
'0/12302B8');
-[ RECORD 1 ]-----+-----
start_lsn      | 0/1230278
end_lsn        | 0/12302B8
prev_lsn       | 0/122FD40
block_id       | 0
reltablespace  | 1663
reldatabase    | 1
relfilenode    | 2658
relforknumber  | 0
relblocknumber | 11
xid            | 341

record_type     | INSERT_LEAF
record_length  | 64
main_data_length | 2
block_data_length | 16
block_fpi_length | 0
block_fpi_info  |
description     | off: 46
block_data      | \x00002a00070010402630000070696400
```

`block_fpi_data` |

This example involves a WAL record that only contains one block reference, but many WAL records contain several block references. Rows output by `pg_get_wal_block_info` are guaranteed to have a unique combination of `start_lsn` and `block_id` values.

Much of the information shown here matches the output that `pg_get_wal_records_info` would show, given the same arguments. However, `pg_get_wal_block_info` unnests the information from each WAL record into an expanded form by outputting one row per block reference, so certain details are tracked at the block reference level rather than at the whole-record level. This structure is useful with queries that track how individual blocks changed over time. Note that records with no block references (e.g., COMMIT WAL records) will have no rows returned, so `pg_get_wal_block_info` may actually return *fewer* rows than `pg_get_wal_records_info`.

The `reltablespace`, `reldatabase`, and `relfilenode` parameters reference `pg_tablespace.oid`, `pg_database.oid`, and `pg_class.relfilenode` respectively. The `relforknumber` field is the fork number within the relation for the block reference; see `common/relpath.h` for details.

### Tip

The `pg_filenode_relation` function (see Table 9.103) can help you to determine which relation was modified during original execution.

It is possible for clients to avoid the overhead of materializing block data. This may make function execution significantly faster. When `show_data` is set to `false`, `block_data` and `block_fpi_data` values are omitted (that is, the `block_data` and `block_fpi_data` OUT arguments are NULL for all rows returned). Obviously, this optimization is only feasible with queries where block data isn't truly required.

The function raises an error if `start_lsn` is not available.

`pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false)` returns setof record

Gets statistics of all the valid WAL records between `start_lsn` and `end_lsn`. By default, it returns one row per `resource_manager` type. When `per_record` is set to `true`, it returns one row per `record_type`. For example:

```
postgres=# SELECT * FROM pg_get_wal_stats('0/1E847D00',
      '0/1E84F500')
      WHERE count > 0 AND
            "resource_manager/record_type" = 'Transaction'
      LIMIT 1;
-[ RECORD 1 ]-----+-----
resource_manager/record_type | Transaction
count                       | 2
count_percentage            | 8
record_size                  | 875
record_size_percentage      | 41.23468426013195
fpi_size                     | 0
fpi_size_percentage         | 0
combined_size                | 875
combined_size_percentage    | 2.8634072910530795
```

The function raises an error if `start_lsn` is not available.

## **F.37.2. Author**

Bharath Rupireddy <bharath.rupireddyforpostgres@gmail.com>

## F.38. `postgres_fdw` — access data stored in external PostgreSQL servers

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external PostgreSQL servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using `CREATE EXTENSION`.
2. Create a foreign server object, using `CREATE SERVER`, to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using `CREATE USER MAPPING`, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using `CREATE FOREIGN TABLE` or `IMPORT FOREIGN SCHEMA`, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `TRUNCATE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the `ONLY` option specified in `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` has no effect when accessing or modifying the remote table.

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

### F.38.1. FDW Options of `postgres_fdw`

#### F.38.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in Section 32.1.2, except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping instead, or use a service file)

- `client_encoding` (this is automatically set from the local server encoding)
- `application_name` - this may appear in *either or both* a connection and `postgres_fdw.application_name`. If both are present, `postgres_fdw.application_name` overrides the connection setting. Unlike `libpq`, `postgres_fdw` allows `application_name` to include “escape sequences”. See `postgres_fdw.application_name` for details.
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Non-superusers may connect to foreign servers using password authentication or with GSSAPI delegated credentials, so specify the `password` option for user mappings belonging to non-superusers where password authentication is required.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required 'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc. in the unix home directory of the system user the postgres server runs as. (For details on how home directories are found, see Section 32.16.) They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

### F.38.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote PostgreSQL server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name` (string)

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name` (string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name` (string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

### F.38.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the

remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate` (boolean)

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is `100`.

`fdw_tuple_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is `0.2`.

When `use_remote_estimate` is true, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is false, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running `ANALYZE` on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

The following option controls how such an `ANALYZE` operation behaves:

`analyze_sampling` (string)

This option, which can be specified for a foreign table or a foreign server, determines if `ANALYZE` on a foreign table samples the data on the remote side, or reads and transfers all data and performs the sampling locally. The supported values are `off`, `random`, `system`, `bernoulli` and `auto`. `off` disables remote sampling, so all data are transferred and sampled locally. `random` performs remote sampling using the `random()` function to choose returned rows, while `system` and `bernoulli` rely on the built-in `TABLESAMPLE` methods of those names. `random` works on all remote server versions, while `TABLESAMPLE` is supported only since 9.5. `auto` (the default) picks the recommended sampling method automatically; currently it means either `bernoulli` or `random` depending on the remote server version.

### F.38.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions` (string)

This option is a comma-separated list of names of PostgreSQL extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are im-

mutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size(integer)`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

`batch_size(integer)`

This option specifies the number of rows `postgres_fdw` should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows `postgres_fdw` inserts at once depends on the number of columns and the provided `batch_size` value. The batch is executed as a single query, and the libpq protocol (which `postgres_fdw` uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns \* `batch_size` exceeds the limit, the `batch_size` will be adjusted to avoid an error.

This option also applies when copying into foreign tables. In that case the actual number of rows `postgres_fdw` copies at once is determined in a similar way to the insert case, but it is limited to at most 1000 due to implementation restrictions of the `COPY` command.

### F.38.1.5. Asynchronous Execution Options

`postgres_fdw` supports asynchronous execution, which runs multiple parts of an `Append` node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

`async_capable(boolean)`

This option controls whether `postgres_fdw` allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `false`.

In order to ensure that the data being returned from a foreign server is consistent, `postgres_fdw` will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an `Append` node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using `postgres_fdw`, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

### F.38.1.6. Transaction Management Options

As described in the Transaction Management section, in `postgres_fdw` transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default `postgres_fdw` commits or aborts those remote transactions serially when

the local transaction is committed or aborted. When multiple remote subtransactions are involved in the current local subtransaction, by default `postgres_fdw` commits or aborts those remote subtransactions serially when the local subtransaction is committed or aborted. Performance can be improved with the following options:

`parallel_commit` (boolean)

This option controls whether `postgres_fdw` commits, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

`parallel_abort` (boolean)

This option controls whether `postgres_fdw` aborts, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is aborted. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

If multiple foreign servers with these options enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed or aborted in parallel across those foreign servers when the local transaction is committed or aborted.

When these options are enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed or aborted.

### F.38.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

### F.38.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

`truncatable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

### F.38.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present

on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate` (boolean)

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default` (boolean)

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated` (boolean)

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null` (boolean)

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although PostgreSQL does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see `CREATE FOREIGN TABLE`.

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from `IMPORT FOREIGN SCHEMA`. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

## F.38.1.10. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

`keep_connections` (boolean)

This option controls whether `postgres_fdw` keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The

default is `on`. If set to `off`, all connections to this foreign server will be discarded at the end of each transaction.

#### `use_scram_passthrough` (boolean)

This option controls whether `postgres_fdw` will use the SCRAM pass-through authentication to connect to the foreign server. With SCRAM pass-through authentication, `postgres_fdw` uses SCRAM-hashed secrets instead of plain-text user passwords to connect to the remote server. This avoids storing plain-text user passwords in PostgreSQL system catalogs.

To use SCRAM pass-through authentication:

- The remote server must request the `scram-sha-256` authentication method; otherwise, the connection will fail.
- The remote server can be of any PostgreSQL version that supports SCRAM. Support for `use_scram_passthrough` is only required on the client side (FDW side).
- The user mapping password is not used.
- The server running `postgres_fdw` and the remote server must have identical SCRAM secrets (encrypted passwords) for the user being used on `postgres_fdw` to authenticate on the foreign server (same salt and iterations, not merely the same password).

As a corollary, if FDW connections to multiple hosts are to be made, for example for partitioned foreign tables/sharding, then all hosts must have identical SCRAM secrets for the users involved.

- The current session on the PostgreSQL instance that makes the outgoing FDW connections also must also use SCRAM authentication for its incoming client connection. (Hence “pass-through”: SCRAM must be used going in and out.) This is a technical requirement of the SCRAM protocol.

## F.38.2. Functions

`postgres_fdw_get_connections( IN check_conn boolean DEFAULT false, OUT server_name text, OUT user_name text, OUT valid boolean, OUT used_in_xact boolean, OUT closed boolean, OUT remote_backend_pid int4)` returns `setof record`

This function returns information about all open connections `postgres_fdw` has established from the local session to foreign servers. If there are no open connections, no records are returned.

If `check_conn` is set to `true`, the function checks the status of each connection and shows the result in the `closed` column. This feature is currently available only on systems that support the non-standard `POLLRDHUP` extension to the `poll` system call, including Linux. This is useful to check if all connections used within a transaction are still open. If any connections are closed, the transaction cannot be committed successfully, so it is better to roll back as soon as a closed connection is detected, rather than continuing to the end. Users can roll back the transaction immediately if the function reports connections where both `used_in_xact` and `closed` are `true`.

Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections(true);
 server_name | user_name | valid | used_in_xact | closed |
 remote_backend_pid
-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
```

|                      |          |   |   |   |  |
|----------------------|----------|---|---|---|--|
| loopback1<br>1353340 | postgres | t | t | f |  |
| loopback2<br>1353120 | public   | t | t | f |  |
| loopback3<br>1353156 |          | f | t | f |  |

The output columns are described in Table F.28.

**Table F.28. postgres\_fdw\_get\_connections Output Columns**

| Column             | Type    | Description                                                                                                                                                                                                                                                         |
|--------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server_name        | text    | The foreign server name of this connection. If the server is dropped but the connection remains open (i.e., marked as invalid), this will be <code>NULL</code> .                                                                                                    |
| user_name          | text    | Name of the local user mapped to the foreign server of this connection, or <code>public</code> if a public mapping is used. If the user mapping is dropped but the connection remains open (i.e., marked as invalid), this will be <code>NULL</code> .              |
| valid              | boolean | False if this connection is invalid, meaning it is used in the current transaction, but its foreign server or user mapping has been changed or dropped. The invalid connection will be closed at the end of the transaction. True is returned otherwise.            |
| used_in_xact       | boolean | True if this connection is used in the current transaction.                                                                                                                                                                                                         |
| closed             | boolean | True if this connection is closed, false otherwise. <code>NULL</code> is returned if <code>check_conn</code> is set to <code>false</code> or if the connection status check is not available on this platform.                                                      |
| remote_backend_pid | int4    | Process ID of the remote backend, on the foreign server, handling the connection. If the remote backend is terminated and the connection is closed (with <code>closed</code> set to <code>true</code> ), this still shows the process ID of the terminated backend. |

`postgres_fdw_disconnect(server_name text)` returns `boolean`

This function discards the open connections that are established by `postgres_fdw` from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local

transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
postgres_fdw_disconnect
-----
t
```

`postgres_fdw_disconnect_all()` returns boolean

This function discards all the open connections that are established by `postgres_fdw` from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
postgres_fdw_disconnect_all
-----
t
```

### F.38.3. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

### F.38.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future PostgreSQL release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

## F.38.5. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

## F.38.6. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see `CREATE FUNCTION`) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

## F.38.7. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1.

A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference

in a sub-SELECT with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

Another limitation is that when executing `INSERT` statements with an `ON CONFLICT DO NOTHING` clause on a foreign table, the remote server must be running PostgreSQL 9.5 or later, as earlier versions do not support this feature.

## F.38.8. Wait Events

`postgres_fdw` can report the following wait events under the wait event type `Extension`:

`PostgresFdwCleanupResult`

Waiting for transaction abort on remote server.

`PostgresFdwConnect`

Waiting to establish a connection to a remote server.

`PostgresFdwGetResult`

Waiting to receive the results of a query from a remote server.

## F.38.9. Configuration Parameters

`postgres_fdw.application_name` (string)

Specifies a value for `application_name` configuration parameter used when `postgres_fdw` establishes a connection to a foreign server. This overrides `application_name` option of the server object. Note that change of this parameter doesn't affect any existing connections until they are re-established.

`postgres_fdw.application_name` can be any string of any length and contain even non-ASCII characters. However when it's passed to and used as `application_name` in a foreign server, note that it will be truncated to less than `NAMEDATALEN` characters. Anything other than printable ASCII characters are replaced with C-style hexadecimal escapes. See `application_name` for details.

% characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it's not allowed to specify a plus/minus sign or a numeric literal after the % and before the option, for alignment and padding.

| Escape | Effect                                                                    |
|--------|---------------------------------------------------------------------------|
| %a     | Application name on local server                                          |
| %C     | Session ID on local server (see <code>log_line_prefix</code> for details) |
| %C     | Cluster name on local server (see <code>cluster_name</code> for details)  |
| %u     | User name on local server                                                 |
| %d     | Database name on local server                                             |
| %p     | Process ID of backend on local server                                     |
| %%     | Literal %                                                                 |

For example, suppose user `local_user` establishes a connection from database `local_db` to foreign\_db as user `foreign_user`, the setting `'db=%d, user=%u'` is replaced with `'db=local_db, user=local_user'`.

## F.38.10. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using `CREATE SERVER`. In this example we wish to connect to a PostgreSQL server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname
'foreign_db');
```

A user mapping, defined with `CREATE USER MAPPING`, is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text
)
    SERVER foreign_server
    OPTIONS (schema_name 'some_schema', table_name
'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

Shigeru Hanada <shigeru.hanada@gmail.com>

## F.39. seg — a datatype for line segments or floating point intervals

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.39.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
      pH
-----
6.25 .. 6.50
(1 row)
```

### F.39.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.29 gives an overview of allowed representations; Table F.30 shows some examples.

In Table F.29,  $x$ ,  $y$ , and  $\delta$  denote floating-point numbers.  $x$  and  $y$ , but not  $\delta$ , can be preceded by a certainty indicator.

**Table F.29. `seg` External Representations**

|                  |                                            |
|------------------|--------------------------------------------|
| $x$              | Single value (zero-length interval)        |
| $x \dots y$      | Interval from $x$ to $y$                   |
| $x (+ -) \delta$ | Interval from $x - \delta$ to $x + \delta$ |
| $x \dots$        | Open interval with lower bound $x$         |
| $\dots x$        | Open interval with upper bound $x$         |

**Table F.30. Examples of Valid `seg` Input**

|                 |                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 5.0             | Creates a zero-length segment (a point, if you will)                                                                                 |
| ~5.0            | Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment. |
| <5.0            | Creates a point at 5.0. < is ignored but is preserved as a comment.                                                                  |
| >5.0            | Creates a point at 5.0. > is ignored but is preserved as a comment.                                                                  |
| 5(+ -)0.3       | Creates an interval 4.7 ... 5.3. Note that the (+ -) notation isn't preserved.                                                       |
| 50 ...          | Everything that is greater than or equal to 50                                                                                       |
| ... 0           | Everything that is less than or equal to 0                                                                                           |
| 1.5e-2 ... 2E-2 | Creates an interval 0.015 ... 0.02                                                                                                   |
| 1 ... 2         | The same as 1...2, or 1 ... 2, or 1..2 (spaces around the range operator are ignored)                                                |

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example 5 ... 2.

## F.39.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

## F.39.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in Table F.31.

**Table F.31. `Seg` GiST Operators**

| Operator                                |
|-----------------------------------------|
| Description                             |
| <code>seg &lt;&lt; seg → boolean</code> |

| Operator                                  | Description                                                                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> .        |
| <code>seg &gt;&gt; seg → boolean</code>   | Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> .       |
| <code>seg &amp;&lt; seg → boolean</code>  | Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code> . |
| <code>seg &amp;&gt; seg → boolean</code>  | Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code> .  |
| <code>seg = seg → boolean</code>          | Are the two <code>segs</code> equal?                                                                                                            |
| <code>seg &amp;&amp; seg → boolean</code> | Do the two <code>segs</code> overlap?                                                                                                           |
| <code>seg @&gt; seg → boolean</code>      | Does the first <code>seg</code> contain the second?                                                                                             |
| <code>seg &lt;@ seg → boolean</code>      | Is the first <code>seg</code> contained in the second?                                                                                          |

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

## F.39.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts (+-) to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
          seg
-----
9.0 .. 11      -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.39.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.40. sepgsql — SELinux-, label-based mandatory access control (MAC) security module

`sepgsql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

### Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.40.7.

### F.40.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by PostgreSQL. From the perspective of SELinux, this module allows PostgreSQL to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by PostgreSQL.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The `SECURITY LABEL` statement allows assignment of a security label to a database object.

### F.40.2. Installation

`sepgsql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need `libselinux` 2.1.10 or higher and `selinux-policy` 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                enabled
SELinuxfs mount:              /selinux
Current mode:                  enforcing
Mode from config file:         enforcing
Policy version:                24
Policy from config file:       targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, specify `--with-selinux` (when using `make` and `autoconf`) or `-Dselinux={ auto | enabled | disabled }` (when using `meson`). Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepgsql` in the `shared_preload_libraries` parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
  change
    #shared_preload_libraries = ''          # (change
requires restart)
  to
    shared_preload_libraries = 'sepgsql'    # (change
requires restart)
$ for DBNAME in template0 template1 postgres; do
  postgres --single -F -c exit_on_error=true $DBNAME \
    </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of `libselinux` and `selinux-policy`:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has
invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has
invalid object type db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

## F.40.3. Regression Tests

The `sepgsql` test suite is run if `PG_TEST_EXTRA` contains `sepgsql` (see Section 31.1.3). This method is suitable during development of PostgreSQL. Alternatively, there is a way to run the tests to check whether a database instance has been set up properly for `sepgsql`.

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root.

The manual tests must be run in the `contrib/sepgsql` directory of a configured PostgreSQL build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in Section F.40.2. Note that the current operating system user must be able to connect to the database as `superuser` without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. (This Makefile is usually supplied by the `selinux-policy-devel` or `selinux-policy` RPM.) Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in `sepgsql-regtest` are not enabled by default; the `sepgsql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See Section F.40.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepgsql` module.

After completing the tests, it's recommended you disable the `sepgsql_regression_test_mode` parameter:

```
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the `sepgsql-regtest` policy entirely:

```
$ sudo semodule -r sepgsql-regtest
```

## F.40.4. GUC Parameters

`sepgsql.permissive` (boolean)

This parameter enables `sepgsql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepgsql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

`sepgsql.debug_audit` (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

## F.40.5. Features

### F.40.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

### F.40.5.2. DML Permissions

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

### F.40.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- `CREATE DATABASE` additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in con-

junction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)

#### F.40.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or `setuid` commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (
           cid      int primary key,
           cname    text,
           credit   text
        );
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit
           IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text
           AS 'SELECT regexp_replace(credit, ''-[0-9]+$'', ''-
xxxx'', 'g')'
           FROM customer WHERE cid = $1'
           LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
           IS
           'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
 cid | cname | show_credit
-----+-----+-----
   1 | taro  | 1111-2222-3333-xxxx
   2 | hanako | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows the user to print the credit card numbers of customers with some of the digits masked out.

#### F.40.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure)

as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```
regression=# select sepysql_getcon();
              sepysql_getcon
-----
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT
  sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c4');
  sepysql_setcon
-----
t
(1 row)

regression=# SELECT
  sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c1023');
ERROR:  SELinux: security policy violation
```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepysql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepysql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

## F.40.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

## F.40.6. Sepysql Functions

Table F.32 shows the available functions.

**Table F.32. Sepysql Functions**

| Function                                    | Description                                                                                                                                                                                                 |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sepysql_getcon()</code> → text        | Returns the client domain, the current security label of the client.                                                                                                                                        |
| <code>sepysql_setcon(text)</code> → boolean | Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client's original domain. |

| Function                                           | Description                                                                                                                                                                       |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sepgsql_mcstrans_in ( text ) → text</code>   | Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.                                                                                   |
| <code>sepgsql_mcstrans_out ( text ) → text</code>  | Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.                                                                                   |
| <code>sepgsql_restorecon ( text ) → boolean</code> | Sets up initial security labels for all objects within the current database. The argument may be NULL, or the name of a specfile to be used as alternative of the system default. |

## F.40.7. Limitations

### Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

### Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

### Row-level access control

PostgreSQL supports row-level access, but `sepgsql` does not.

### Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

## F.40.8. External Resources

### SE-PostgreSQL Introduction<sup>8</sup>

This wiki page provides a brief overview, security design, architecture, administration and upcoming features.

### SELinux User's and Administrator's Guide<sup>9</sup>

This document provides a wide spectrum of knowledge to administer SELinux on your systems. It focuses primarily on Red Hat operating systems, but is not limited to them.

### Fedora SELinux FAQ<sup>10</sup>

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

## F.41. spi — Server Programming Interface features/examples

The `spi` module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

### F.41.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create an `AFTER INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create an `AFTER DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

Note that if these triggers are executed from another `BEFORE` trigger, they can fail unexpectedly. For example, if a user inserts row1 and then the `BEFORE` trigger inserts row2 and calls a trigger with the `check_foreign_key()`, the `check_foreign_key()` function will not see row1 and will fail.

There are examples in `refint.example`.

### F.41.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same. The trigger will replace the field's value only if that value is initially zero or null (after the action of the SQL statement that inserted or updated the row). Also, if the sequence's next value is zero, `nextval()` will be called a second time in order to obtain a non-zero value.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

### F.41.3. `insert_username` — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

### F.41.4. `moddatetime` — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

## F.42. sslinfo — obtain client SSL information

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to PostgreSQL. The module is useless (most functions will return `NULL`) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

### F.42.1. Functions Provided

`ssl_is_used()` returns `boolean`

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns `text`

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher()` returns `text`

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns `boolean`

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns `numeric`

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns `text`

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the `SQL_ASCII` encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns `text`

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

## F.43. tablefunc — functions that return tables (crosstab and others)

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.43.1. Functions Provided

Table F.33 summarizes the functions provided by the `tablefunc` module.

**Table F.33. tablefunc Functions**

| Function                                                                                                                                                                        | Description                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>normal_rand ( numvals integer, mean float8, stddev float8 ) → setof float8</code>                                                                                         | Produces a set of normally distributed random values.                                                                                                                                                                                                      |
| <code>crosstab ( sql text ) → setof record</code>                                                                                                                               | Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.                                                                                                    |
| <code>crosstabN ( sql text ) → setof table_crosstab_N</code>                                                                                                                    | Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below. |
| <code>crosstab ( source_sql text, category_sql text ) → setof record</code>                                                                                                     | Produces a “pivot table” with the value columns specified by a second query.                                                                                                                                                                               |
| <code>crosstab ( sql text, N integer ) → setof record</code>                                                                                                                    | Obsolete version of <code>crosstab ( text )</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.                                                                                   |
| <code>connectby ( relname text, keyid_fld text, parent_keyid_fld text [, order-by_fld text ], start_with text, max_depth integer [, branch_delim text ] ) → setof record</code> | Produces a representation of a hierarchical tree structure.                                                                                                                                                                                                |

#### F.43.1.1. normal\_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

*numvals* is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
normal_rand
-----
 1.56556322244898
 9.100409991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
      .
      .
      .
 4.82992125404908
 9.71308014517282
 2.49639286969028
(1000 rows)
```

### F.43.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
row_name  cat    value
-----+-----+-----
row1      cat1    val1
row1      cat2    val2
row1      cat3    val3
row1      cat4    val4
```

|      |      |      |
|------|------|------|
| row2 | cat1 | val5 |
| row2 | cat2 | val6 |
| row2 | cat3 | val7 |
| row2 | cat4 | val8 |

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text,
category_2 text);
```

This example produces a set something like:

```

      <== value columns ==>
row_name  category_1  category_2
-----+-----+-----
row1      val1       val2
row2      val5       val6
```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att4','val8');

SELECT *
```

```
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3
text);
```

| row_name | category_1 | category_2 | category_3 |
|----------|------------|------------|------------|
| test1    | val2       | val3       |            |
| test2    | val6       | val7       |            |

(2 rows)

You can avoid always having to write out a **FROM** clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required **FROM** clause in a view definition.

### Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

## F.43.1.3. `crosstabN(text)`

`crosstabN(text sql)`

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling **SELECT** query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
  row_name TEXT,
  category_1 TEXT,
  category_2 TEXT,
  .
  .
  .
  category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *
FROM crosstab3(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
```

```
order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one text parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (  
    my_row_name text,  
    my_category_1 float8,  
    my_category_2 float8,  
    my_category_3 float8,  
    my_category_4 float8,  
    my_category_5 float8  
);  
  
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
    RETURNS setof my_crosstab_float8_5_cols  
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
    IN text,  
    OUT my_row_name text,  
    OUT my_category_1 float8,  
    OUT my_category_2 float8,  
    OUT my_category_3 float8,  
    OUT my_category_4 float8,  
    OUT my_category_5 float8)  
    RETURNS setof record  
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

#### F.43.1.4. `crosstab(text, text)`

`crosstab(text source_sql, text category_sql)`

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

*source\_sql* is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, *source\_sql* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

| row_name | extra_col | cat  | value |
|----------|-----------|------|-------|
| row1     | extra1    | cat1 | val1  |
| row1     | extra1    | cat2 | val2  |
| row1     | extra1    | cat4 | val4  |
| row2     | extra2    | cat1 | val5  |
| row2     | extra2    | cat2 | val6  |
| row2     | extra2    | cat3 | val7  |
| row2     | extra2    | cat4 | val8  |

*category\_sql* is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. *category\_sql* might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat
-----
cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3
text, cat4 text);
```

This will produce a result something like:

|          |        | <==  | value | columns | ==>  |
|----------|--------|------|-------|---------|------|
| row_name | extra  | cat1 | cat2  | cat3    | cat4 |
| row1     | extra1 | val1 | val2  |         | val4 |
| row2     | extra2 | val5 | val6  | val7    | val8 |

The `FROM` clause must define the proper number of output columns of the proper data types. If there are *N* columns in the *source\_sql* query's result, the first *N-2* of them must match up with the first *N-2* output columns. The remaining output columns must have the type of the last column of the *source\_sql* query's result, and there must be exactly as many of them as there are rows in the *category\_sql* query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching `category` values. If a row's `category` does not match any output of the *category\_sql* query, its `value` is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *source\_sql* query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *category\_sql* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);
year | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct
 | Nov | Dec
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
2007 | 1000 | 1500 |      |      |      |      | 500 |      |      |      |
 | 1500 | 2000
2008 | 1000 |      |      |      |      |      |      |      |      |      |
 |      |
(2 rows)
```

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val
text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March
2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March
2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01
March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
```

```

AS
(
    rowid text,
    rowdt timestamp,
    temperature int4,
    test_result text,
    test_startdate timestamp,
    volts float8
);
rowid |          rowdt          | temperature | test_result |
test_startdate | volts
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS          |
          | 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL          | Sat
Mar 01 00:00:00 2003 | 3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named `crosstab_hash`.

### F.43.1.5. connectby

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.34 explains the parameters.

**Table F.34. connectby Parameters**

| Parameter               | Description                                              |
|-------------------------|----------------------------------------------------------|
| <i>relname</i>          | Name of the source relation                              |
| <i>keyid_fld</i>        | Name of the key field                                    |
| <i>parent_keyid_fld</i> | Name of the parent-key field                             |
| <i>orderby_fld</i>      | Name of the field to order siblings by (optional)        |
| <i>start_with</i>       | Key value of the row to start at                         |
| <i>max_depth</i>        | Maximum depth to descend to, or zero for unlimited depth |
| <i>branch_delim</i>     | String to separate keys with in branch output (optional) |

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start\_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid',
    'pos', 'row2', 0, '~')
    AS t(keyid text, parent_keyid text, level int, branch text, pos
    int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a *branch\_delim* parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an *orderby\_fld* parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch\_delim* string. If no branch display is wanted, omit both the *branch\_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *orderby\_fld* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *orderby\_fld* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *branch\_delim* string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if *branch\_delim* is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos
    int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not
-- guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid',
    'row2', 0, '~')
    AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level |      branch
-----+-----+-----+-----
row2  |              |      0 | row2
row4  | row2         |      1 | row2~row4

```

## F.43.2. Author

Joe Conway

## F.44. tcn — a trigger function to notify listeners of changes to table content

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER` trigger `FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(#   a int not null,
test(#   b date not null,
test(#   c text,
test(#   primary key (a, b)
test(# );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=# after insert or update or delete on tcndata
test=# for each row execute function
test=#   triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                                     (1, date '2012-12-23',
test=#                                     'another'),
test=#                                     (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload
""tcndata",I,"a"='1',"b"='2012-12-22'" received from server
process with PID 22770.
Asynchronous notification "tcn" with payload
""tcndata",I,"a"='1',"b"='2012-12-23'" received from server
process with PID 22770.
Asynchronous notification "tcn" with payload
""tcndata",I,"a"='2',"b"='2012-12-23'" received from server
process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload
""tcndata",U,"a"='1',"b"='2012-12-22'" received from server
process with PID 22770.
```

```
Asynchronous notification "tcn" with payload
""tcndata",U,"a"='1',"b"='2012-12-23'" received from server
process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload
""tcndata",D,"a"='1',"b"='2012-12-22'" received from server
process with PID 22770.
```

## F.45. test\_decoding — SQL-based test/example module for WAL logical decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot',
  NULL, NULL, 'include-xids', '0');
   lsn    | xid | data
-----+-----
0/16D30F8 | 691 | BEGIN
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2
data[text]: 'arg'
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3
data[text]: 'demo'
0/16D32A0 | 691 | COMMIT
0/16D32D8 | 692 | BEGIN
0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=#* SELECT * FROM
  pg_logical_slot_get_changes('test_slot', NULL, NULL, 'stream-
changes', '1');
   lsn    | xid | data
-----+-----
0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
0/16B21F8 | 503 | streaming change for TXN 503
0/16B2300 | 503 | streaming change for TXN 503
0/16B2408 | 503 | streaming change for TXN 503
0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
0/16BECA8 | 503 | streaming change for TXN 503
0/16BEDB0 | 503 | streaming change for TXN 503
0/16BEEB8 | 503 | streaming change for TXN 503
0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
(10 rows)
```

## F.46. `tsm_system_rows` — the `SYSTEM_ROWS` sampling method for `TABLESAMPLE`

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.46.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

## F.47. `tsm_system_time` — the `SYSTEM_TIME` sampling method for `TABLESAMPLE`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.47.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

## F.48. unaccent — a text search dictionary which removes diacritics

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.48.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the PostgreSQL installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

|   |    |
|---|----|
| À | A  |
| Á | A  |
| Â | A  |
| Ã | A  |
| Ä | A  |
| Å | A  |
| Æ | AE |

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- Some characters, like numeric symbols, may require whitespaces in their translation rule. It is possible to use double quotes around the translated characters in this case. A double quote needs to be escaped with a second double quote when including one in the translated character. For example:

|   |         |
|---|---------|
| ¼ | " 1/4"  |
| ½ | " 1/2"  |
| ¾ | " 3/4"  |
| " | " "" "" |
| " | " "" "" |

- As with other PostgreSQL text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded.

Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

## F.48.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
      ts_lexize
-----
{Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
      to_tsvector
-----
'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@
      to_tsquery('fr','Hotels');
      ?column?
-----
t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la
      Mer',to_tsquery('fr','Hotels'));
      ts_headline
-----
<b>Hôtel</b> de la Mer
(1 row)
```

## F.48.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns `text`

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');  
SELECT unaccent('Hôtel');
```

## F.49. uuid-ossdp — a UUID generator

The `uuid-ossdp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.49.1. uuid-ossdp Functions

Table F.35 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122<sup>11</sup> specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F.35. Functions for UUID Generation**

| Function                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_generate_v1()</code> → <code>uuid</code>                          | Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.                                                                                                                                                                                                                                                                                                                                      |
| <code>uuid_generate_v1mc()</code> → <code>uuid</code>                        | Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>uuid_generate_v3(namespace uuid, name text)</code> → <code>uuid</code> | Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> ( ) functions shown in Table F.36. (It could be any UUID in theory.) The name is an identifier in the selected namespace.<br>For example:<br><br><pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http:// www.postgresql.org');</pre><br>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible. |
| <code>uuid_generate_v4()</code> → <code>uuid</code>                          | Generates a version 4 UUID, which is derived entirely from random numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>uuid_generate_v5(namespace uuid, name text)</code> → <code>uuid</code> | Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table F.36. Functions Returning UUID Constants**

| Function                            | Description                                                                                                                                                            |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_nil () → uuid</code>     | Returns a “nil” UUID constant, which does not occur as a real UUID.                                                                                                    |
| <code>uuid_ns_dns () → uuid</code>  | Returns a constant designating the DNS namespace for UUIDs.                                                                                                            |
| <code>uuid_ns_url () → uuid</code>  | Returns a constant designating the URL namespace for UUIDs.                                                                                                            |
| <code>uuid_ns_oid () → uuid</code>  | Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in PostgreSQL.) |
| <code>uuid_ns_x500 () → uuid</code> | Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.                                                                                  |

## F.49.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=oss` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

## F.49.3. Author

Peter Eisentraut <[peter\\_e@gmx.net](mailto:peter_e@gmx.net)>

## F.50. xml2 — XPath querying and XSLT functionality

The `xml2` module provides XPath querying and XSLT functionality.

### F.50.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of PostgreSQL in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to `<pgsql-hacker-s@lists.postgresql.org>` so that the deficiency can be addressed.

### F.50.2. Description of Functions

Table F.37 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

**Table F.37. `xml2` Functions**

| Function                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xml_valid ( document text ) → boolean</code>                                         | Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard PostgreSQL function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)                                                                                |
| <code>xpath_string ( document text, query text ) → text</code>                             | Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .                                                                                                                                                                                                                                                                                               |
| <code>xpath_number ( document text, query text ) → real</code>                             | Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .                                                                                                                                                                                                                                                                                               |
| <code>xpath_bool ( document text, query text ) → boolean</code>                            | Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .                                                                                                                                                                                                                                                                                            |
| <code>xpath_nodeset ( document text, query text, toptag text, itemtag text ) → text</code> | Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like: <pre> &lt;toptag&gt; &lt;itemtag&gt;Value 1 which could be an XML fragment&lt;/itemtag&gt; &lt;itemtag&gt;Value 2....&lt;/itemtag&gt; &lt;/toptag&gt; </pre> <p>If either <i>toptag</i> or <i>itemtag</i> is an empty string, the relevant tag is omitted.</p> |
| <code>xpath_nodeset ( document text, query text, itemtag text ) → text</code>              | Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits <i>toptag</i> .                                                                                                                                                                                                                                                                                            |
| <code>xpath_nodeset ( document text, query text ) → text</code>                            |                                                                                                                                                                                                                                                                                                                                                                                               |

| Function                                                                  | Description                                                                                                                                                            |
|---------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                           | Like <code>xpath_node_set(document, query, toptag, itemtag)</code> but result omits both tags.                                                                         |
| <code>xpath_list(document text, query text, separator text) → text</code> | Evaluates the query on the document and returns multiple values separated by the specified separator, for example Value 1, Value 2, Value 3 if <i>separator</i> is , . |
| <code>xpath_list(document text, query text) → text</code>                 | This is a wrapper for the above function that uses , as the separator.                                                                                                 |

## F.50.3. xpath\_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria)` returns set of record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.38.

**Table F.38. xpath\_table Parameters**

| Parameter       | Description                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>key</i>      | the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values) |
| <i>document</i> | the name of the field containing the XML document                                                                                                                                                            |
| <i>relation</i> | the name of the table or view containing the documents                                                                                                                                                       |
| <i>xpaths</i>   | one or more XPath expressions, separated by                                                                                                                                                                  |
| <i>criteria</i> | the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation                                                   |

These parameters (except the XPath strings) are just substituted into a plain SQL `SELECT` statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this `SELECT` needs to return exactly two columns (which it will unless you try to list multiple fields for `key` or `document`). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a `FROM` expression, with an `AS` clause to specify the output columns; for example

```
SELECT * FROM
  xpath_table('article_id',
             'article_xml',
             'articles',
             '/article/author|/article/pages|/article/title',
```

```
        'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title
text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml, '/article/@date') >
                ''2003-03-20'' ')
    AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.50.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
```

```
</doc>');
```

```
SELECT * FROM
  xpath_table('id', 'xml', 'test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/
doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int,
      val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

| id | doc_num | line_num | val1 | val2 | val3 |
|----|---------|----------|------|------|------|
| 1  | C1      | L1       | 1    | 2    | 3    |
| 1  |         | L2       | 11   | 22   | 33   |

To get doc\_num on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3
int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

| id | line_num | val1 | val2 | val3 | doc_num |
|----|----------|------|------|------|---------|
| 1  | L1       | 1    | 2    | 3    | C1      |
| 1  | L2       | 11   | 22   | 33   | C1      |

(2 rows)

## F.50.4. XSLT Functions

The following functions are available if `libxslt` is installed:

### F.50.4.1. `xslt_process`

```
xslt_process(text document, text stylesheet, text paramlist)
returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

## F.50.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. ([www.torchbox.com](http://www.torchbox.com)). It has the same BSD license as PostgreSQL.

---

# Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the `contrib` directory of the PostgreSQL distribution. See Appendix F for more information about the `contrib` section in general and server extensions and plug-ins found in `contrib` specifically.

This appendix covers utility programs found in `contrib`. Once installed, either from source or a packaging system, they are found in the `bin` directory of the PostgreSQL installation and can be used like any other program.

## G.1. Client Applications

This section covers PostgreSQL client applications in `contrib`. They can be run from anywhere, independent of where the database server resides. See also PostgreSQL Client Applications for information about client applications that are part of the core PostgreSQL distribution.

## oid2name

oid2name — resolve OIDs and file nodes in a PostgreSQL data directory

## Synopsis

oid2name [*option...*]

## Description

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 66.

### Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

## Options

oid2name accepts the following command-line arguments:

**-f** *filenode*

**--filenode=***filenode*

show info for table with filenode *filenode*.

**-i**

**--indexes**

include indexes and sequences in the listing.

**-o** *oid*

**--oid=***oid*

show info for table with OID *oid*.

**-q**

**--quiet**

omit headers (useful for scripting).

**-s**

**--tablespaces**

show tablespace OIDs.

**-S**

**--system-objects**

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

`-t tablename_pattern`  
`--table=tablename_pattern`

show info for table(s) matching *tablename\_pattern*.

`-V`  
`--version`

Print the oid2name version and exit.

`-x`  
`--extended`

display more information about each object shown: tablespace name, schema name, and OID.

`-?`  
`--help`

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d database`  
`--dbname=database`

database to connect to.

`-h host`  
`--host=host`

database server's host.

`-H host`

database server's host. Use of this parameter is *deprecated* as of PostgreSQL 12.

`-p port`  
`--port=port`

database server's port.

`-U username`  
`--username=username`

user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `f00%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-S` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

## Environment

PGHOST  
PGPORT  
PGUSER

Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

`oid2name` requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

## Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
  Oid Database Name Tablespace
-----
 17228      alvherre pg_default
 17255      regression pg_default
 17227      template0 pg_default
    1      template1 pg_default

$ oid2name -s
All tablespaces:
  Oid Tablespace Name
-----
  1663      pg_default
  1664      pg_global
 155151      fastdisk
 155152      bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by
size
$ ls -ls * | head -10

  tablespace.
$ cd 155151/17228
$ ls -l
total 0
-rw-----  1 postgres postgres 0 sep 13 23:20 155156

$ # OK, this is a pretty small table ... but which one is it?
$ oid2name -d alvherre -f 155156
From database "alvherre":
  Filenode  Table Name
-----
      155156          foo
```

## Author

B. Palmer <bpalmer@crimelabs.net>

## vacuumlo

vacuumlo — remove orphaned large objects from a PostgreSQL database

## Synopsis

```
vacuumlo [option...] dbname...
```

## Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the `lo` module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

## Options

vacuumlo accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding `max_locks_per_transaction`. Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the vacuumlo version and exit.

```
-?  
--help
```

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

`-p port`  
`--port=port`

Database server's port.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

`PGHOST`  
`PGPORT`  
`PGUSER`

Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

## Author

Peter Mount <peter@retep.org.uk>

## G.2. Server Applications

Some applications run on the PostgreSQL server itself. Currently, no such applications are included in the `contrib` directory. See also PostgreSQL Server Applications for information about server applications that are part of the core PostgreSQL distribution.

---

# Appendix H. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

## H.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. A list of language interfaces<sup>1</sup> is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

[https://wiki.postgresql.org/wiki/List\\_of\\_drivers](https://wiki.postgresql.org/wiki/List_of_drivers)

## H.2. Administration Tools

There are several administration tools available for PostgreSQL. The most popular is pgAdmin<sup>2</sup>, and there are several commercially available ones as well.

## H.3. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. A list of procedural languages<sup>3</sup> is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

[https://wiki.postgresql.org/wiki/PL\\_Matrix](https://wiki.postgresql.org/wiki/PL_Matrix)

## H.4. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The `contrib/` directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS<sup>4</sup>. Even PostgreSQL replication solutions can be developed externally. For example, Slony-I<sup>5</sup> is a popular primary/standby replication solution that is developed independently from the core project.

# Appendix I. The Source Code Repository

The PostgreSQL source code is stored and managed using the Git version control system. A public mirror of the master repository is available; it is updated within a minute of any change to the master repository.

Our wiki, [https://wiki.postgresql.org/wiki/Working\\_with\\_Git](https://wiki.postgresql.org/wiki/Working_with_Git), has some discussion on working with Git.

## I.1. Getting the Source via Git

With Git you will make a copy of the entire code repository on your local machine, so you will have access to all history and branches offline. This is the fastest and most flexible way to develop or test patches.

### Git

1. You will need an installed version of Git, which you can get from <https://git-scm.com>. Many systems already have a recent version of Git installed by default, or available in their package distribution system.
2. To begin using the Git repository, make a clone of the official mirror:

```
git clone https://git.postgresql.org/git/postgresql.git
```

This will copy the full repository to your local machine, so it may take a while to complete, especially if you have a slow Internet connection. The files will be placed in a new subdirectory `postgresql` of your current directory.

3. Whenever you want to get the latest updates in the system, `cd` into the repository, and run:

```
git fetch
```

Git can do a lot more things than just fetch the source. For more information, consult the Git man pages, or see the website at <https://git-scm.com>.

---

# Appendix J. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF, for printing
- man pages, for quick reference.

Additionally, a number of plain-text README files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF format documentation is available separately for download.

## J.1. DocBook

The documentation sources are written in *DocBook*, which is a markup language defined in XML. In what follows, the terms DocBook and XML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group<sup>1</sup>. The official DocBook site<sup>2</sup> has good introductory and reference documentation and a complete O'Reilly book for your online reading pleasure. The FreeBSD Documentation Project<sup>3</sup> also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

## J.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD<sup>4</sup>

This is the definition of DocBook itself. We currently use version 4.5; you cannot use later or earlier versions. You need the XML variant of the DocBook DTD, not the SGML variant.

DocBook XSL Stylesheets<sup>5</sup>

These contain the processing instructions for converting the DocBook sources to other formats, such as HTML.

The minimum required version is currently 1.77.0, but it is recommended to use the latest available version for best results.

Libxml2<sup>6</sup> for `xmllint`

This library and the `xmllint` tool it contains are used for processing XML. Many developers will already have Libxml2 installed, because it is also used when building the PostgreSQL code. Note, however, that `xmllint` might need to be installed from a separate subpackage.

---

<sup>1</sup> <https://www.oasis-open.org>

<sup>2</sup> <https://www.oasis-open.org/docbook/>

<sup>3</sup> <https://www.freebsd.org/docproj/>

<sup>4</sup> <https://www.oasis-open.org/docbook/>

<sup>5</sup> <https://github.com/docbook/wiki/wiki/DocBookXslStylesheets>

<sup>6</sup> <http://xmlsoft.org/>

Libxslt<sup>7</sup> for xsltproc

xsltproc is an XSLT processor, that is, a program to convert XML to other formats using XSLT stylesheets.

FOP<sup>8</sup>

This is a program for converting, among other things, XML to PDF. It is needed only if you want to build the documentation in PDF format.

We have documented experience with several installation methods for the various tools that are needed to process the documentation. These will be described below. There might be some other packaged distributions for these tools. Please report package status to the documentation mailing list, and we will include that information here.

## J.2.1. Installation on Fedora, RHEL, and Derivatives

To install the required packages, use:

```
yum install docbook-dtds docbook-style-xsl libxslt fop
```

## J.2.2. Installation on FreeBSD

To install the required packages with pkg, use:

```
pkg install docbook-xml docbook-xsl libxslt fop
```

When building the documentation from the doc directory you'll need to use gmake, because the makefile provided is not suitable for FreeBSD's make.

## J.2.3. Debian Packages

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

```
apt-get install docbook-xml docbook-xsl libxml2-utils xsltproc fop
```

## J.2.4. macOS

If you use MacPorts, the following will get you set up:

```
sudo port install docbook-xml docbook-xsl-nons libxslt fop
```

If you use Homebrew, use this:

```
brew install docbook docbook-xsl libxslt fop
```

The Homebrew-supplied programs require the following environment variable to be set. For Intel based machines, use this:

---

<sup>7</sup> <http://xmlsoft.org/XSLT/>

<sup>8</sup> <https://xmlgraphics.apache.org/fop/>

```
export XML_CATALOG_FILES=/usr/local/etc/xml/catalog
```

On Apple Silicon based machines, use this:

```
export XML_CATALOG_FILES=/opt/homebrew/etc/xml/catalog
```

Without it, `xsltproc` will throw errors like this:

```
I/O error : Attempt to load network entity http://www.oasis-
open.org/docbook/xml/4.5/docbookx.dtd
postgres.sgml:21: warning: failed to load external entity "http://
www.oasis-open.org/docbook/xml/4.5/docbookx.dtd"
...
```

While it is possible to use the Apple-provided versions of `xmllint` and `xsltproc` instead of those from MacPorts or Homebrew, you'll still need to install the DocBook DTD and stylesheets, and set up a catalog file that points to them.

## J.2.5. Detection by configure

Before you can build the documentation you need to run the `configure` script, as you would when building the PostgreSQL programs themselves. Check the output near the end of the run; it should look something like this:

```
checking for xmllint... xmllint
checking for xsltproc... xsltproc
checking for fop... fop
checking for dbtoepub... dbtoepub
```

If `xmllint` or `xsltproc` is not found, you will not be able to build any of the documentation. `fop` is only needed to build the documentation in PDF format. `dbtoepub` is only needed to build the documentation in EPUB format.

If necessary, you can tell `configure` where to find these programs, for example

```
./configure ... XMLLINT=/opt/local/bin/xmllint ...
```

If you prefer to build PostgreSQL using Meson, instead run `meson setup` as described in Section 17.4, and then see Section J.4.

## J.3. Building the Documentation with Make

Once you have everything set up, change to the directory `doc/src/sgml` and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU `make`.)

### J.3.1. HTML

To build the HTML version of the documentation:

```
doc/src/sgml$ make html
```

This is also the default target. The output appears in the subdirectory `html`.

To produce HTML documentation with the stylesheet used on [postgresql.org](https://www.postgresql.org/docs/current/)<sup>9</sup> instead of the default simple style use:

```
doc/src/sgml$ make STYLE=website html
```

If the `STYLE=website` option is used, the generated HTML files include references to stylesheets hosted on [postgresql.org](https://www.postgresql.org/docs/current/)<sup>10</sup> and require network access to view.

## J.3.2. Manpages

We use the DocBook XSL stylesheets to convert DocBook `refentry` pages to `*roff` output suitable for man pages. To create the man pages, use the command:

```
doc/src/sgml$ make man
```

## J.3.3. PDF

To produce a PDF rendition of the documentation using FOP, you can use one of the following commands, depending on the preferred paper format:

- For A4 format:

```
doc/src/sgml$ make postgres-A4.pdf
```

- For U.S. letter format:

```
doc/src/sgml$ make postgres-US.pdf
```

Because the PostgreSQL documentation is fairly big, FOP will require a significant amount of memory. Because of that, on some systems, the build will fail with a memory-related error message. This can usually be fixed by configuring Java heap settings in the configuration file `~/foprc`, for example:

```
# FOP binary distribution
FOP_OPTS='-Xmx1500m'
# Debian
JAVA_ARGS='-Xmx1500m'
# Red Hat
ADDITIONAL_FLAGS='-Xmx1500m'
```

There is a minimum amount of memory that is required, and to some extent more memory appears to make things a bit faster. On systems with very little memory (less than 1 GB), the build will either be very slow due to swapping or will not work at all.

In its default configuration FOP will emit an `INFO` message for each page. The log level can be changed via `~/foprc`:

```
LOGCHOICE=-Dorg.apache.commons.logging.Log=
org.apache.commons.logging.impl.SimpleLog
LOGLEVEL=-Dorg.apache.commons.logging.simplelog.defaultlog=WARN
```

---

<sup>9</sup> <https://www.postgresql.org/docs/current/>

<sup>10</sup> <https://www.postgresql.org/docs/current/>

Other XSL-FO processors can also be used manually, but the automated build process only supports FOP.

### J.3.4. Syntax Check

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

```
doc/src/sgml$ make check
```

## J.4. Building the Documentation with Meson

To build the documentation using Meson, change to the `build` directory before running one of these commands, or add `-C build` to the command.

To build just the HTML version of the documentation:

```
build$ ninja html
```

For a list of other documentation targets see Section 17.4.4.3. The output appears in the subdirectory `build/doc/src/sgml`.

## J.5. Documentation Authoring

The documentation sources are most conveniently modified with an editor that has a mode for editing XML, and even more so if it has some awareness of XML schema languages so that it can know about DocBook syntax specifically.

Note that for historical reasons the documentation source files are named with an extension `.sgml` even though they are now XML files. So you might need to adjust your editor configuration to set the correct mode.

### J.5.1. Emacs

nXML Mode, which ships with Emacs, is the most common mode for editing XML documents with Emacs. It will allow you to use Emacs to insert tags and check markup consistency, and it supports DocBook out of the box. Check the nXML manual<sup>11</sup> for detailed documentation.

`src/tools/editors/emacs.samples` contains recommended settings for this mode.

## J.6. Style Guide

### J.6.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

---

<sup>11</sup> [https://www.gnu.org/software/emacs/manual/html\\_mono/nxml-mode.html](https://www.gnu.org/software/emacs/manual/html_mono/nxml-mode.html)

## Name

This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

## Synopsis

This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

## Description

Several paragraphs explaining what the command does.

## Options

A list describing each command-line option. If there are a lot of options, subsections can be used.

## Exit Status

If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

## Usage

Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

## Environment

List all environment variables that the program might use. Try to be complete; even seemingly trivial variables like `SHELL` might be of interest to the user.

## Files

List any files that the program might access implicitly. That is, do not list input and output files that were specified on the command line, but list configuration files, etc.

## Diagnostics

Explain any unusual output that the program might create. Refrain from listing every possible error message. This is a lot of work and has little use in practice. But if, say, the error messages have a standard format that the user can parse, this would be the place to explain it.

## Notes

Anything that doesn't fit elsewhere, but in particular bugs, implementation flaws, security considerations, compatibility issues.

## Examples

Examples

## History

If there were some major milestones in the history of the program, they might be listed here. Usually, this section can be omitted.

## Author

Author (only used in the contrib section)

## See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages, PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference pages (e.g., operating system, other packages), other documentation. Items in the same group are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis, Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters section is like the Options section, but there is more freedom about which clauses of the command can be listed. The Outputs section is only needed if the command returns something other than a default command-completion tag. The Compatibility section should explain to what extent this command conforms to the SQL standard(s), or to which other database system it is compatible. The See Also section of SQL commands should list SQL commands before cross-references to programs.

---

# Appendix K. PostgreSQL Limits

Table K.1 describes various hard limits of PostgreSQL. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

**Table K.1. PostgreSQL Limitations**

| Item                    | Upper Limit                                                           | Comment                                                                |
|-------------------------|-----------------------------------------------------------------------|------------------------------------------------------------------------|
| database size           | unlimited                                                             |                                                                        |
| number of databases     | 4,294,950,911                                                         |                                                                        |
| relations per database  | 1,431,650,303                                                         |                                                                        |
| relation size           | 32 TB                                                                 | with the default <code>BLCKSZ</code> of 8192 bytes                     |
| rows per table          | limited by the number of tuples that can fit onto 4,294,967,295 pages |                                                                        |
| columns per table       | 1,600                                                                 | further limited by tuple size fitting on a single page; see note below |
| columns in a result set | 1,664                                                                 |                                                                        |
| field size              | 1 GB                                                                  |                                                                        |
| indexes per table       | unlimited                                                             | constrained by maximum relations per database                          |
| columns per index       | 32                                                                    | can be increased by recompiling PostgreSQL                             |
| partition keys          | 32                                                                    | can be increased by recompiling PostgreSQL                             |
| identifier length       | 63 bytes                                                              | can be increased by recompiling PostgreSQL                             |
| function arguments      | 100                                                                   | can be increased by recompiling PostgreSQL                             |
| query parameters        | 65,535                                                                |                                                                        |

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of  $2^{32}$  out-of-line values; see Section 66.2 for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down `INSERT/UPDATE` statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

# Appendix M. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACID                         | <i>Atomicity, Consistency, Isolation, and Durability.</i> This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.                                                                                                                                                                                                                                                                                           |
| Aggregate function (routine) | <i>A function</i> that combines ( <i>aggregates</i> ) multiple input values, for example by counting, averaging or adding, yielding a single output value.<br><br>For more information, see Section 9.21.<br><br>See Also Window function (routine).                                                                                                                                                                                                                                                            |
| Access Method                | Interfaces which PostgreSQL use in order to access data in tables and indexes. This abstraction allows for adding support for new types of data storage.<br><br>For more information, see Chapter 62 and Chapter 63.                                                                                                                                                                                                                                                                                            |
| Analytic function            | See Window function (routine).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Analyze (operation)          | The act of collecting statistics from data in <i>tables</i> and other <i>relations</i> to help the <i>query planner</i> to make decisions about how to execute <i>queries</i> .<br><br>(Don't confuse this term with the ANALYZE option to the EXPLAIN command.)<br><br>For more information, see ANALYZE.                                                                                                                                                                                                      |
| Asynchronous I/O (AIO)       | Asynchronous I/O (AIO) describes performing I/O in a non-blocking way (asynchronously), in contrast to synchronous I/O, which blocks for the entire duration of the I/O.<br><br>With AIO, starting an I/O operation is separated from waiting for the result of the operation, allowing multiple I/O operations to be initiated concurrently, as well as performing CPU heavy operations concurrently with I/O. The price for that increased concurrency is increased complexity.<br><br>See Also Input/Output. |
| Atomic                       | In reference to a <i>datum</i> : the fact that its value cannot be broken down into smaller components.<br><br>In reference to a <i>database transaction</i> : see <i>atomicity</i> .                                                                                                                                                                                                                                                                                                                           |
| Atomicity                    | The property of a <i>transaction</i> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.                                                                                                                                                                                                                                     |
| Attribute                    | An element with a certain name and data type found within a <i>tuple</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Autovacuum (process)         | A set of background processes that routinely perform <i>vacuum</i> and <i>analyze</i> operations. The <i>auxiliary process</i> that coordinates the                                                                                                                                                                                                                                                                                                                                                             |

work and is always present (unless autovacuum is disabled) is known as the *autovacuum launcher*, and the processes that carry out the tasks are known as the *autovacuum workers*.

For more information, see Section 24.1.6.

Auxiliary process

A process within an *instance* that is in charge of some specific background task for the instance. The auxiliary processes consist of the *autovacuum launcher* (but not the autovacuum workers), the *background writer*, the *checkpointer*, the *logger*, the *startup process*, the *WAL archiver*, the *WAL receiver* (but not the *WAL senders*), the *WAL summarizer*, and the *WAL writer*.

Backend (process)

Process of an *instance* which acts on behalf of a *client session* and handles its requests.

(Don't confuse this term with the similar terms *Background Worker* or *Background Writer*).

Background worker (process)

Process within an *instance*, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as *logical replication* and *parallel queries*. In addition, *Extensions* can add custom background worker processes.

For more information, see Chapter 46.

Background writer (process)

An *auxiliary process* that writes dirty *data pages* from *shared memory* to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.

For more information, see Section 19.4.4.

Base Backup

A binary copy of all *database cluster* files. It is generated by the tool `pg_basebackup`. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.

Bloat

Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.

Bootstrap superuser

The first *user* initialized in a *database cluster*.

This user owns all system catalog tables in each database. It is also the role from which all granted permissions originate. Because of these things, this role may not be dropped.

This role also behaves as a normal *database superuser*, and its superuser status cannot be removed.

Buffer Access Strategy

Some operations will access a large number of *pages*. A *Buffer Access Strategy* helps to prevent these operations from evicting too many pages from *shared buffers*.

A Buffer Access Strategy sets up references to a limited number of *shared buffers* and reuses them circularly. When the operation requires a new page, a victim buffer is chosen from the buffers in the strategy ring, which may require flushing the page's dirty data and possibly also unflushed WAL to permanent storage.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | Buffer Access Strategies are used for various operations such as sequential scans of large tables, <code>VACUUM</code> , <code>COPY</code> , <code>CREATE TABLE AS SELECT</code> , <code>ALTER TABLE</code> , <code>CREATE DATABASE</code> , <code>CREATE INDEX</code> , and <code>CLUSTER</code> .                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Cast                   | <p>A conversion of a <i>datum</i> from its current data type to another data type.</p> <p>For more information, see <code>CREATE CAST</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Catalog                | <p>The SQL standard uses this term to indicate what is called a <i>database</i> in PostgreSQL's terminology.</p> <p>(Don't confuse this term with <i>system catalog</i>).</p> <p>For more information, see Section 22.1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check constraint       | <p>A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i>. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.</p> <p>For more information, see Section 5.5.</p>                                                                                                                                                                                                                                                                                                                                                               |
| Checkpoint             | <p>A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i> modified before that checkpoint; a <i>checkpoint record</i> is written and flushed to <i>WAL</i> to mark that point.</p> <p>A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command <code>CHECKPOINT</code>.</p> <p>For more information, see Section 28.5.</p> |
| Checkpointer (process) | An <i>auxiliary process</i> that is responsible for executing <i>checkpoints</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Class (archaic)        | See <i>Relation</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Client (process)       | Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Cluster owner          | <p>The operating system user that owns the <i>data directory</i> and under which the <code>postgres</code> process is run. It is required that this user exist prior to creating a new <i>database cluster</i>.</p> <p>On operating systems with a <code>root</code> user, said user is not allowed to be the cluster owner.</p>                                                                                                                                                                                                                                                                                                                                                                                    |
| Column                 | An <i>attribute</i> found in a <i>table</i> or <i>view</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Commit                 | <p>The act of finalizing a <i>transaction</i> within the <i>database</i>, which makes it visible to other transactions and assures its <i>durability</i>.</p> <p>For more information, see <code>COMMIT</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Concurrency                  | The concept that multiple independent operations happen within the <i>database</i> at the same time. In PostgreSQL, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.                                                                                                                                                                                                                                                                                                                                     |
| Connection                   | <p>An established line of communication between a client process and a <i>backend</i> process, usually over a network, supporting a <i>session</i>. This term is sometimes used as a synonym for session.</p> <p>For more information, see Section 19.3.</p>                                                                                                                                                                                                                                                                                |
| Consistency                  | The property that the data in the <i>database</i> is always in compliance with <i>integrity constraints</i> . Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically <i>rolled back</i> . This is one of the ACID properties.                                                                                                                                                                    |
| Constraint                   | <p>A restriction on the values of data allowed within a <i>table</i>, or in attributes of a <i>domain</i>.</p> <p>For more information, see Section 5.5.</p>                                                                                                                                                                                                                                                                                                                                                                                |
| Cumulative Statistics System | <p>A system which, if enabled, accumulates statistical information about the <i>instance's</i> activities.</p> <p>For more information, see Section 27.2.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| Data area                    | See Data directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Database                     | <p>A named collection of <i>local SQL objects</i>.</p> <p>For more information, see Section 22.1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Database cluster             | <p>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>. A database cluster is created using the <code>initdb</code> program.</p> <p>In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)</p> <p>See also <i>cluster owner</i>, the operating-system owner of a cluster, and <i>bootstrap superuser</i>, the PostgreSQL owner of a cluster.</p> |
| Database server              | See Instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Database superuser           | <p>A role having <i>superuser status</i> (see Section 21.2).</p> <p>Frequently referred to as <i>superuser</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Data directory               | <p>The base directory on the file system of a <i>server</i> that contains all data files and subdirectories associated with a <i>database cluster</i> (with the exception of <i>tablespaces</i>, and optionally <i>WAL</i>). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory.</p> <p>A <i>cluster's</i> storage space comprises the data directory plus any additional tablespaces.</p> <p>For more information, see Section 66.1.</p>                                                         |

|                          |                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data page                | <p>The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <i>shared buffers</i> where they can be modified, becoming <i>dirty</i>. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.</p> |
| Datum                    | <p>The internal representation of one value of an SQL data type.</p>                                                                                                                                                                                                                                                                                                         |
| Delete                   | <p>An SQL command which removes <i>rows</i> from a given <i>table</i> or <i>relation</i>.</p> <p>For more information, see DELETE.</p>                                                                                                                                                                                                                                       |
| Domain                   | <p>A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values.</p> <p>For more information, see Section 8.18.</p>                                                                                                                                             |
| Durability               | <p>The assurance that once a <i>transaction</i> has been <i>committed</i>, the changes remain even after a system failure or crash. This is one of the ACID properties.</p>                                                                                                                                                                                                  |
| Epoch                    | <p>See Transaction ID.</p>                                                                                                                                                                                                                                                                                                                                                   |
| Extension                | <p>A software add-on package that can be installed on an <i>instance</i> to get extra features.</p> <p>For more information, see Section 36.17.</p>                                                                                                                                                                                                                          |
| File segment             | <p>A physical file which stores data for a given <i>relation</i>. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.</p> <p>For more information, see Section 66.1.</p> <p>(Don't confuse this term with the similar term <i>WAL segment</i>).</p>                   |
| Foreign data wrapper     | <p>A means of representing data that is not contained in the local <i>database</i> so that it appears as if were in local <i>table(s)</i>. With a foreign data wrapper it is possible to define a <i>foreign server</i> and <i>foreign tables</i>.</p> <p>For more information, see CREATE FOREIGN DATA WRAPPER.</p>                                                         |
| Foreign key              | <p>A type of <i>constraint</i> defined on one or more <i>columns</i> in a <i>table</i> which requires the value(s) in those <i>columns</i> to identify zero or one <i>row</i> in another (or, infrequently, the same) <i>table</i>.</p>                                                                                                                                      |
| Foreign server           | <p>A named collection of <i>foreign tables</i> which all use the same <i>foreign data wrapper</i> and have other configuration values in common.</p> <p>For more information, see CREATE SERVER.</p>                                                                                                                                                                         |
| Foreign table (relation) | <p>A <i>relation</i> which appears to have <i>rows</i> and <i>columns</i> similar to a regular <i>table</i>, but will forward requests for data through its <i>foreign data wrapper</i>, which will return <i>result sets</i> structured according to the definition of the <i>foreign table</i>.</p>                                                                        |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | For more information, see CREATE FOREIGN TABLE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Fork                  | Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <i>free space map</i> and the <i>visibility map</i> . <i>Unlogged relations</i> also have an <i>init fork</i> .                                                                                                                                                                                                                                                        |
| Free space map (fork) | <p>A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.</p> <p>For more information, see Section 66.3.</p>                                                                                                                                                                                                      |
| Function (routine)    | <p>A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <b>SELECT</b>. Certain functions can return <i>sets</i>; those are called <i>set-returning functions</i>.</p> <p>Functions can also be used for <i>triggers</i> to invoke.</p> <p>For more information, see CREATE FUNCTION.</p>                                                                                                                  |
| GMT                   | See UTC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Grant                 | <p>An SQL command that is used to allow a <i>user</i> or <i>role</i> to access specific objects within the <i>database</i>.</p> <p>For more information, see GRANT.</p>                                                                                                                                                                                                                                                                                                                                                                                      |
| Heap                  | Contains the values of <i>row</i> attributes (i.e., the data) for a <i>relation</i> . The heap is realized within one or more <i>file segments</i> in the relation's <i>main fork</i> .                                                                                                                                                                                                                                                                                                                                                                      |
| Host                  | A computer that communicates with other computers over a network. This is sometimes used as a synonym for <i>server</i> . It is also used to refer to a computer where <i>client processes</i> run.                                                                                                                                                                                                                                                                                                                                                          |
| Index (relation)      | <p>A <i>relation</i> that contains data derived from a <i>table</i> or <i>materialized view</i>. Its internal structure supports fast retrieval of and access to the original data.</p> <p>For more information, see CREATE INDEX.</p>                                                                                                                                                                                                                                                                                                                       |
| Incremental backup    | <p>A special <i>base backup</i> that for some files may contain only those pages that were modified since a previous backup, as opposed to the full contents of every file. Like base backups, it is generated by the tool <code>pg_basebackup</code>.</p> <p>To restore incremental backups the tool <code>pg_combinebackup</code> is used, which combines incremental backups with a base backup. Afterwards, recovery can use <i>WAL</i> to bring the <i>database cluster</i> to a consistent state.</p> <p>For more information, see Section 25.3.3.</p> |
| Input/Output (I/O)    | Input/Output (I/O) describes the communication between a program and peripheral devices. In the context of database systems, I/                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | <p>O commonly, but not exclusively, refers to interaction with storage devices or the network.</p> <p>See Also Asynchronous I/O.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Insert                      | <p>An SQL command used to add new data into a <i>table</i>.</p> <p>For more information, see INSERT.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Instance                    | <p>A group of <i>backend</i> and <i>auxiliary processes</i> that communicate using a common shared memory area. One <i>postmaster process</i> manages the instance; one instance manages exactly one <i>database cluster</i> with all its databases. Many instances can run on the same <i>server</i> as long as their TCP ports do not conflict.</p> <p>The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, <i>connections</i> to <i>client processes</i>, privilege verification, crash recovery, replication, etc.</p> |
| Isolation                   | <p>The property that the effects of a transaction are not visible to <i>concurrent transactions</i> before it commits. This is one of the ACID properties.</p> <p>For more information, see Section 13.2.</p>                                                                                                                                                                                                                                                                                                                                                                                              |
| Join                        | <p>An operation and SQL keyword used in <i>queries</i> for combining data from multiple <i>relations</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Key                         | <p>A means of identifying a <i>row</i> within a <i>table</i> or other <i>relation</i> by values contained within one or more <i>attributes</i> in that relation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Lock                        | <p>A mechanism that allows a process to limit or prevent simultaneous access to a resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Log file                    | <p>Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.</p> <p>For more information, see Section 24.3.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Logged                      | <p>A <i>table</i> is considered <i>logged</i> if changes to it are sent to the WAL. By default, all regular tables are logged. A table can be specified as <i>unlogged</i> either at creation time or via the ALTER TABLE command.</p>                                                                                                                                                                                                                                                                                                                                                                     |
| Logger (process)            | <p>An <i>auxiliary process</i> which, if enabled, writes information about database events into the current <i>log file</i>. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <i>syslogger</i>.</p> <p>For more information, see Section 19.8.</p>                                                                                                                                                                                                                                                                                                         |
| Logical replication cluster | <p>A set of publisher and subscriber instances with the publisher instance replicating changes to the subscriber instance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Log record                  | <p>Archaic term for a WAL <i>record</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Log sequence number (LSN)   | <p>Byte offset into the WAL, increasing monotonically with each new WAL <i>record</i>.</p> <p>For more information, see <code>pg_lsn</code> and Section 28.6.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| LSN                                      | See Log sequence number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Master (server)                          | See Primary (server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Materialized                             | <p>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.</p> <p>This term is used in <i>materialized view</i>, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</p> <p>This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</p>                                                                                                    |
| Materialized view (relation)             | <p>A <i>relation</i> that is defined by a <code>SELECT</code> statement (just like a <i>view</i>), but stores data in the same way that a <i>table</i> does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, or <code>MERGE</code> operations.</p> <p>For more information, see <code>CREATE MATERIALIZED VIEW</code>.</p>                                                                                                                                                                                                                                                                                          |
| Merge                                    | <p>An SQL command used to conditionally add, modify, or remove rows in a given <i>table</i>, using data from a source <i>relation</i>.</p> <p>For more information, see <code>MERGE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Multi-version concurrency control (MVCC) | A mechanism designed to allow several <i>transactions</i> to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies ( <i>versions</i> ) of <i>tuples</i> as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.                                                                                                                                                                                                                                                                                  |
| Null                                     | A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Optimizer                                | See Query planner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Parallel query                           | The ability to handle parts of executing a <i>query</i> to take advantage of parallel processes on servers with multiple CPUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Partition                                | <p>One of several disjoint (not overlapping) subsets of a larger set.</p> <p>In reference to a <i>partitioned table</i>: One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i>. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.</p> <p>In reference to a <i>window function</i> in a <i>query</i>, a partition is a user-defined criterion that identifies which neighboring <i>rows</i> of the <i>query's result set</i> can be considered by the function.</p> |
| Partitioned table (relation)             | A <i>relation</i> that is in semantic terms the same as a <i>table</i> , but whose storage is distributed across several <i>partitions</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Postmaster (process)                     | The very first process of an <i>instance</i> . It starts and manages the <i>auxiliary processes</i> and creates <i>backend processes</i> on demand.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

For more information, see Section 18.3.

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Primary key           | A special case of a <i>unique constraint</i> defined on a <i>table</i> or other <i>relation</i> that also guarantees that all of the <i>attributes</i> within the <i>primary key</i> do not have <i>null</i> values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.                                                                                                     |
| Primary (server)      | When two or more <i>databases</i> are linked via <i>replication</i> , the <i>server</i> that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .                                                                                                                                                                                                                                                                               |
| Procedure (routine)   | A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as <code>COMMIT</code> and <code>ROLLBACK</code> . They are invoked via the <code>CALL</code> command.<br><br>For more information, see <code>CREATE PROCEDURE</code> .                                                                                                                                                                      |
| Query                 | A request sent by a client to a <i>backend</i> , usually to return results or to modify data on the database.                                                                                                                                                                                                                                                                                                                                                                                   |
| Query planner         | The part of PostgreSQL that is devoted to determining ( <i>planning</i> ) the most efficient way to execute <i>queries</i> . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .                                                                                                                                                                                                                                                                               |
| Record                | See <i>Tuple</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Recycling             | See <i>WAL file</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Referential integrity | A means of restricting data in one <i>relation</i> by a <i>foreign key</i> so that it must have matching data in another <i>relation</i> .                                                                                                                                                                                                                                                                                                                                                      |
| Relation              | <p>The generic term for all objects in a <i>database</i> that have a name and a list of <i>attributes</i> defined in a specific order. <i>Tables</i>, <i>sequences</i>, <i>views</i>, <i>foreign tables</i>, <i>materialized views</i>, composite types, and <i>indexes</i> are all relations.</p> <p>More generically, a relation is a set of tuples; for example, the result of a query is also a relation.</p> <p>In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.</p> |
| Replica (server)      | A <i>database</i> that is paired with a <i>primary</i> database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the <i>primary</i> becomes unavailable.                                                                                                                                                                   |
| Replication           | The act of reproducing data on one <i>server</i> onto another server called a <i>replica</i> . This can take the form of <i>physical replication</i> , where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.                                                                                                                                                       |
| Restartpoint          | A variant of a <i>checkpoint</i> performed on a <i>replica</i> .<br><br>For more information, see Section 28.5.                                                                                                                                                                                                                                                                                                                                                                                 |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Result set | <p>A <i>relation</i> transmitted from a <i>backend process</i> to a <i>client</i> upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, or <code>MERGE</code> command if the <code>RETURNING</code> clause is specified.</p> <p>The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.</p>                 |
| Revoke     | <p>A command to prevent access to a named set of <i>database</i> objects for a named list of <i>roles</i>.</p> <p>For more information, see <code>REVOKE</code>.</p>                                                                                                                                                                                                                                                                                                                       |
| Role       | <p>A collection of access privileges to the <i>instance</i>. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple <i>users</i> need the same privileges.</p> <p>For more information, see <code>CREATE ROLE</code>.</p>                                                                                                                                                                         |
| Rollback   | <p>A command to undo all of the operations performed since the beginning of a <i>transaction</i>.</p> <p>For more information, see <code>ROLLBACK</code>.</p>                                                                                                                                                                                                                                                                                                                              |
| Routine    | <p>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be <i>functions</i> (including set-returning functions and <i>trigger functions</i>), <i>aggregate functions</i>, and <i>procedures</i>.</p> <p>Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</p>                                                    |
| Row        | <p>See Tuple.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Savepoint  | <p>A special mark in the sequence of steps in a <i>transaction</i>. Data modifications after this point in time may be reverted to the time of the savepoint.</p> <p>For more information, see <code>SAVEPOINT</code>.</p>                                                                                                                                                                                                                                                                 |
| Schema     | <p>A schema is a namespace for <i>SQL objects</i>, which all reside in the same <i>database</i>. Each SQL object must reside in exactly one schema.</p> <p>All system-defined SQL objects reside in schema <code>pg_catalog</code>.</p> <p>More generically, the term <i>schema</i> is used to mean all data descriptions (<i>table</i> definitions, <i>constraints</i>, comments, etc.) for a given <i>database</i> or subset thereof.</p> <p>For more information, see Section 5.10.</p> |
| Segment    | <p>See File segment.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Select     | <p>The SQL command used to request data from a <i>database</i>. Normally, <code>SELECT</code> commands are not expected to modify the <i>database</i> in any way, but it is possible that <i>functions</i> invoked within the query could have side effects that do modify data.</p>                                                                                                                                                                                                       |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                     | For more information, see <code>SELECT</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Sequence (relation) | A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <i>primary key</i> values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Server              | <p>A computer on which PostgreSQL <i>instances</i> run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>.</p> <p>This term is sometimes used to refer to an instance or to a host.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session             | A state that allows a client and a backend to interact, communicating over a <i>connection</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Shared memory       | <p>RAM which is used by the processes common to an <i>instance</i>. It mirrors parts of <i>database</i> files, provides a transient area for <i>WAL records</i>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</p> <p>The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.</p> <p>For more information, see Section 19.4.1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SQL object          | <p>Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as <i>local objects</i>.</p> <p>Most local objects reside in a specific <i>schema</i> in their containing database, such as <i>relations</i> (all types), <i>routines</i> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</p> <p>There also exist local objects that do not reside in schemas; some examples are <i>extensions</i>, <i>data type casts</i>, and <i>foreign data wrappers</i>. The names of such objects of the same type are enforced to be unique within the database.</p> <p>Other object types, such as <i>roles</i>, <i>tablespaces</i>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster.</p> <p>For more information, see Section 22.1.</p> |
| SQL standard        | A series of documents that define the SQL language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Standby (server)    | See <code>Replica (server)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Startup process     | <p>An <i>auxiliary process</i> that replays WAL during crash recovery and in a <i>physical replica</i>.</p> <p>(The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Superuser       | As used in this documentation, it is a synonym for <i>database superuser</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| System catalog  | <p>A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see Chapter 35) that expose some of the same and additional information as mandated by the <i>SQL standard</i>.</p> <p>For more information, see Section 5.10.</p> |
| Table           | <p>A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in PostgreSQL.</p> <p>For more information, see CREATE TABLE.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| Tablespace      | <p>A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all <i>SQL objects</i>, called <code>pg_default</code>.</p> <p>For more information, see Section 22.6.</p>                                                                                                                                                                                                                                                                                              |
| Temporary table | <p><i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i>. Temporary tables are often used to store intermediate data for a multi-step operation.</p> <p>For more information, see CREATE TABLE.</p>                                                                                                                                                                                                                                                                                                                                   |
| TOAST           | <p>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table.</p> <p>For more information, see Section 66.2.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Transaction     | <p>A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level.</p> <p>For more information, see Section 13.2.</p>                                                                                                                                                                                                                                                                                                                                                        |
| Transaction ID  | <p>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, <i>epochs</i> are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value; see Section 67.1 for more details.</p>      |

For more information, see Section 8.19.

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transactions per second (TPS) | Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.                                                                                                                                                                                                                                                                               |
| Trigger                       | <p>A <i>function</i> which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a <i>relation</i>. A trigger executes within the same <i>transaction</i> as the statement which invoked it, and if the function fails, then the invoking statement also fails.</p> <p>For more information, see CREATE TRIGGER.</p>                                                                                                         |
| Tuple                         | A collection of <i>attributes</i> in a fixed order. That order may be defined by the <i>table</i> (or other <i>relation</i> ) where the tuple is contained, in which case the tuple is often called a <i>row</i> . It may also be defined by the structure of a result set, in which case it is sometimes called a <i>record</i> .                                                                                                                                             |
| Unique constraint             | <p>A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.</p> <p>Because <i>null values</i> are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.</p> |
| Unlogged                      | <p>The property of certain <i>relations</i> that the changes to them are not reflected in the WAL. This disables replication and crash recovery for these relations.</p> <p>The primary use of unlogged tables is for storing transient work data that must be shared across processes.</p> <p><i>Temporary tables</i> are always unlogged.</p>                                                                                                                                |
| Update                        | <p>An SQL command used to modify <i>rows</i> that may already exist in a specified <i>table</i>. It cannot create or remove rows.</p> <p>For more information, see UPDATE.</p>                                                                                                                                                                                                                                                                                                 |
| User                          | A <i>role</i> that has the <i>login privilege</i> (see Section 21.2).                                                                                                                                                                                                                                                                                                                                                                                                          |
| User mapping                  | <p>The translation of login credentials in the local <i>database</i> to credentials in a remote data system defined by a <i>foreign data wrapper</i>.</p> <p>For more information, see CREATE USER MAPPING.</p>                                                                                                                                                                                                                                                                |
| UTC                           | Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).                                                                                                                                                                                                                                                                           |
| Vacuum                        | The process of removing outdated <i>tuple versions</i> from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of MVCC. This can be initiated                                                                                                                                                                                                                                                                          |

through the use of the `VACUUM` command, but can also be handled automatically via *autovacuum* processes.

For more information, see Section 24.1 .

**View** A *relation* that is defined by a `SELECT` statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see `CREATE VIEW`.

**Visibility map (fork)** A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (`all-visible`) indicates that all tuples in the page are visible to all transactions. The second one (`all-frozen`) indicates that all tuples in the page are marked frozen.

**WAL** See Write-ahead log.

**WAL archiver (process)** An *auxiliary process* which, if enabled, saves copies of *WAL files* for the purpose of creating backups or keeping *replicas* current.

For more information, see Section 25.3.

**WAL file** Also known as *WAL segment* or *WAL segment file*. Each of the sequentially-numbered files that provide storage space for WAL. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.

Each WAL file can be released after a *checkpoint* writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called *recycling*.

For more information, see Section 28.6.

**WAL record** A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (*replayed*) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.

For more information, see Section 28.6.

**WAL receiver (process)** An *auxiliary process* that runs on a *replica* to receive WAL from the *primary server* for replay by the *startup process*.

For more information, see Section 26.2.

**WAL segment** See WAL file.

**WAL sender (process)** A special *backend process* that streams WAL over a network. The receiving end can be a *WAL receiver* in a *replica*, `pg_receivewal`, or any other client program that speaks the replication protocol.

**WAL summarizer (process)** An *auxiliary process* that summarizes WAL data for *incremental backups*.

For more information, see Section 19.5.7.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WAL writer (process)      | <p>An <i>auxiliary process</i> that writes <i>WAL records</i> from <i>shared memory</i> to <i>WAL files</i>.</p> <p>For more information, see Section 19.5.</p>                                                                                                                                                                                                                                                                                                                                  |
| Window function (routine) | <p>A type of <i>function</i> used in a <i>query</i> that applies to a <i>partition</i> of the query's <i>result set</i>; the function's result is based on values found in <i>rows</i> of the same partition or frame.</p> <p>All <i>aggregate functions</i> can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <i>analytic functions</i>.</p> <p>For more information, see Section 3.5.</p> |
| Write-ahead log           | <p>The journal that keeps track of the changes in the <i>database cluster</i> as user- and system-invoked operations take place. It comprises many individual <i>WAL records</i> written sequentially to <i>WAL files</i>.</p>                                                                                                                                                                                                                                                                   |

# Appendix N. Color Support

Most programs in the PostgreSQL package can produce colorized console output. This appendix describes how that is configured.

## N.1. When Color is Used

To use colorized output, set the environment variable `PG_COLOR` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

## N.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *key=value* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

**error**

used to highlight the text “error” in error messages

**warning**

used to highlight the text “warning” in warning messages

**note**

used to highlight the text “detail” and “hint” in such messages

**locus**

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:note=01;36:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01;36 = bold cyan, 01 = bold default color).

### Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

---

# Appendix O. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

## O.1. `recovery.conf` file merged into `postgresql.conf`

PostgreSQL 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in PostgreSQL 12. See the release notes for PostgreSQL 12 for details on this change.

On PostgreSQL 12 and above, archive recovery, streaming replication, and PITR are configured using normal server configuration parameters. These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

PostgreSQL 15 and below had a setting `promote_trigger_file`, or `trigger_file` before 12. Use `pg_ctl promote` or call `pg_promote()` to promote a standby instead.

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See Standby Server Operation for details.

## O.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See Section 21.5 for current documentation regarding Predefined Roles, and the release notes for PostgreSQL 14 for details on this change.

## O.3. `pg_xlogdump` renamed to `pg_waldump`

PostgreSQL 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see `pg_waldump` for documentation of `pg_waldump` and see the release notes for PostgreSQL 10 for details on this change.

## O.4. `pg_resetxlog` renamed to `pg_resetwal`

PostgreSQL 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see `pg_resetwal` for documentation of `pg_resetwal` and see the release notes for PostgreSQL 10 for details on this change.

## O.5. `pg_receivexlog` renamed to `pg_receivewal`

PostgreSQL 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see `pg_receivewal` for documentation of `pg_receivewal` and see the release notes for PostgreSQL 10 for details on this change.
